Contents of this report have been approved by the World Agricultural Outlook Board, and the summary was released August 19, 1986. Materials may be reprinted without permission. *Agricultural Outlook* is published monthly, except for the January/February combined issue. Price and quantity forecasts for crops are based on the August 12 World Agriculture Supply and Demand Estimates.

Annual subscriptions: \$26 U.S., \$32.50 foreign. Order from ERS Publications, 1301 New York Ave., NW, Room 228, Washington, D.C. 20005-4789. Make check payable to ERS Publications. You will receive a copy of the current issue and acknowledgement of your subscription order. For further information, call (202) 786-1494. Subscriptions also available from the Government Printing Office; for information, call the GPO order desk at (202) 783-3238.

The next issue of *Agricultural Outlook* (AO-124) is scheduled for mailing on October 3, 1986. If you do not receive AO-124 by October 17, call the Managing Editor (be sure to have your mailing label handy). The full text and tables of AO-124 will also be available electronically. For more information, write EMS/USDA, 1301 New York Avenue, N.W., Room 228, Washington, D.C. 20005-4789, or call (202) 786-1494.

In Brief. . . Milk Production Technology and Conservation Reserve Signup

U.S. agriculture is continuing its transition to the new policies of the 1985 farm act. Since January, wheat and corn prices have dropped about 25 percent, soybean prices are down about 20 cents, and rice and cotton prices have dropped more than half. The lower prices are leading to increased export sales. But burdensome U.S. stocks of feed grain and soybeans will probably grow even larger during 1986/87, while wheat stocks are not likely to fall substantially.

Total domestic output for most of the ten major field crops will be less this season than in recent years. For most crops, declines resulted from reduced plantings brought about by increased participation in commodity programs.

The season-long drought in the Southeast and, to a lesser extent, the hot, dry weather that developed at midseason in the Delta, Kentucky, and Tennessee, had a severe effect on regional crop production. But for most major field crops, particularly food and feed grains, the regional adverse weather has had a negligible national impact.

Growing conditions were good to excellent through mid-August in the Midwest and Northern Plains, where the bulk of the U.S. corn, soybean, and spring wheat crops is grown. Consequently, above-average production in these regions is offsetting losses due to the drought.

Bovine growth hormone (bGH) is a technological breakthrough that could increase milk production greatly. In test herds, yield increases of 7 to 28 percent annually have been observed. At milk prices of about \$12.50 per cwt, at least a 6-percent increase in production would be needed to make use profitable. Though bGH has not yet received FDA approval for commercial use, its adoption could mean fewer cows and dairy farmers needed. Lower milk prices might then result from increased supplies and lower production costs.

Net cash income for the farm sector in 1986 is forecast at \$43 to \$47 billion, little changed from the record-high \$44.0 billion in 1985. Direct payments to the farm sector will total a record \$10 to \$13 billion in 1986, and net CCC loans will add another \$8 to \$12 billion. The 5- to 7-percent decline in 1986 farm production expenses will lower cash expenses to the 1980 level.

Part of U.S. agriculture's financial situation is bleak, but fruit and vegetable farmers are thought to be prospering. Prices for most fruits and vegetables have not fallen the way wheat, corn, and soybean prices have. Fresh produce consumption has been growing, and fruit and vegetable farmers are less dependent than grain farmers on the vagaries of export markets.

Argentina and Brazil are adopting divergent agricultural policies which may affect U.S. exports. Argentina is the world's second largest exporter of grains, oilseeds, and oilseed products, but currently uses only a fraction of its production potential. If taxes on agricultural exports are eliminated and investments in the marketing

infrastructure are increased, Argentina could boost its exports substantially by 1990. However, low world grain prices could dampen increases.

On the other hand, changes in Brazilian agricultural policy favor increased stock holding and are shifting Government incentives away from export crops. Brazil's actions may result in its losing some share of the world market in soybeans and products. However, this will probably be offset by higher domestic food-crop production, resulting in smaller grain imports.

Two major factors set the stage for faster economic growth in 1986: a declining dollar and falling interest rates. By the end of 1985, the dollar had fallen 20 percent against a basket of currencies, and against some individual currencies the decline was even more dramatic. The declines tended to make imported goods more expensive to U.S. consumers, while making U.S. goods less expensive to foreigners. The result should have been falling imports and rising exports, which in turn should have spurred U.S. production and employment.

However, the first half of 1986 simply did not conform to the pattern most analysts expected. Industrial production declined 1.8 percent, capacity utilization declined 2.6 percentage points, and employment grew only slowly.

The Conservation Reserve Program has enrollment goals of 5 million acres during the 1986 crop year and 40 to 45 million acres by 1990, but only 3.8 million acres were signed up in March and May. Enrollment in the reserve will likely accelerate during subsequent signups as farmers become better informed about the program and the range of bids acceptable. Experience with the Soil Bank Program of the 1950's suggests that the CRP goal of 40 to 45 million acres can be met.

Agricultural Economy

U.S. agriculture is continuing its transition to the new policies of the 1985 farm act. Since January, wheat and corn prices have dropped about 25 percent, soybean prices are down about 20 cents, and rice and cotton prices have dropped more than half. The lower prices are leading to increased export sales. But burdensome U.S. stocks of feed grain and soybeans will probably grow even larger during 1986/87, while wheat stocks are not likely to fall substantially.

The 1985 Food Security Act is designed to boost the U.S. share of export markets by allowing prices for major program commodities to drop to competitive levels. Without U.S. loan rates propping up world prices, there will be less incentive for foreign production. At the same time, U.S. production is being limited by annual acreage reduction programs and the long-term conservation reserve program. Lower U.S. crop prices could also boost domestic feed use, as livestock, poultry, and dairy producers respond to cheaper production costs.

It will take time for the new programs to work. U.S. exports are beginning to recover, but the increases for feed grains and soybeans will probably not be enough to reduce ending stocks in 1986/87 (table 17). Foreign production of wheat, rice, and soybeans is expected to rise, not fall, during 1986/87 (table 25). And U.S. feed use

1986/87 Wheat and Corn Beginning Stocks

Crop	Total	Farmer-owned reserve	COC inventory	Outstanding loans and special programs	Free stocks
Million bushels					
Wheat	1,900	433	602	841	24
Corn	4,013	550	600	2,750	113

Forecast Results of the New Farm Bill During 1986/87

Crop	Level of price support 1/	Percent change from 1985/86 Production	Exports	Ending stocks
Wheat	-30	-11	26	-3
Corn	-28	-6	27	34
Soybeans	n.a.	-6	1	14
Rice	-55	-8	45	-17
Cotton	-61	-20	220	-26

1/ Wheat: \$3.30 to \$2.30; corn: \$2.55 to \$1.84; soybeans: not announced; rice: \$8.00 to \$3.60 (\$3.60 = 50 percent of \$7.20 loan rate); cotton: \$.573 to \$.224 (\$.224 = announced world price as of August 1. USDA does not forecast cotton prices).

during 1986/87 is likely to be about the same as 1985/86, since meat supplies are expected to remain high while dairy program adjustments continue.

The crops most likely to benefit first from new programs are cotton and rice. Exports of both are rising rapidly, production is falling, and stocks are being reduced. The common factors are relative certainty about the programs and competitive prices.

Cotton and Rice Programs Determined by Law

The Secretary of Agriculture is required to estimate the world prices of rice and cotton, and then implement those programs to ensure that U.S. prices are competitive with world prices. Consequently, the policy outlines of the rice and cotton programs are relatively clear.

On the other hand, traders have been less certain about the wheat, feed grain, and soybean programs, since the authority to allow below-loan-rate repayment of loans for those commodities is discretionary. Even though policies have been announced, the existence of discretionary authority has led to speculation over policy direction, and traders have been reluctant to take market positions.

Another reason rice and cotton export sales are much above a year ago is that the farm act places no floor under 1986-crop cotton prices, and the floor under rice prices is only 50 percent of the \$7.20-per-cwt. average loan rate. For wheat, feed grain, and soybeans, the 1986/87 loan rates are lower than in 1985/86, but the loans must be repaid in full when being redeemed, unless commodity certificates are used. As a result, some support under U.S. prices still exists.

A factor affecting U.S. wheat sales is that only about 1 percent of wheat stocks on June 1 were not in reserve, Government inventory, or used as collateral for loans. In contrast, free stocks of corn are expected to total about 3 percent of total stocks when the marketing year begins September 1. The amount of grain available to the market is being boosted by the new-crop harvest and in-kind payments (generic certificates) from the Government. Still, U.S. wheat prices remain near the Gramm-Rudman-Hollings adjusted loan rate, while corn prices will probably be well below the loan rate when the corn year begins.

A fourth factor affecting U.S. exports is growing foreign supplies. Even though foreign consumption is rising, the ratios of supply to use in foreign countries are expected to remain high during 1986/87.

Wheat and Corn Prices

	Loan rate 1/ 1986/87	Prices Dollars per bushel
Wheat	2.30	2.29 2/
Corn	1.84	1.64 3/

1/ Includes 4.3 percent Gramm-Rudman-Hollings reduction. 2/ Average farm price for all wheat during first-half July. 3/ Average closing price of the September futures contract in Chicago, August 1-19.

The forecast 26- to 220-percent export increases for grains and cotton during 1986/87 represent a greater first-year response to price changes than might normally be expected to occur. However, before U.S. exports of wheat, feed grains, and soybeans can rise enough to lower stocks, the difference between foreign supply and foreign use must widen. Several years of low commodity prices and greater certainty about U.S. policies will be required to achieve those export goals. *[Terry Townsend (202) 786-3313]*

LIVESTOCK HIGHLIGHTS

•Cattle

Cattle numbers on July 1, at 112.2 million head, were 4 percent below a year ago and the lowest since the midyear series began in 1973. Increased cow slaughter and low heifer retention resulted in the total cow herd declining 3 percent, with the beef and dairy herds declining 3 and 2 percent, respectively.

Through early July, the year's cumulative weekly dairy cow slaughter was 35 percent above a year ago. Beef cow slaughter was 3 percent below the same period. Although overall beef cow slaughter has declined, as a proportion of the beginning-cow inventory it is above a year ago.

While expansion is not indicated, there are signs that the cattle inventory may stabilize at about 100 to 101 million head in January 1987. The number of beef heifers being retained for possible herd expansion was 2 percent below a year ago, but the rate of decline was well below 1985's 11 percent.

The estimated 1986 calf crop dropped 2 percent to 40.1 million head, the lowest since 1960 and the sixth con-

secutive year of decline. Calves available to go on feed for stocker operations or slaughter were down 4 percent, while the yearling supply fell 1 percent.

Cattle on feed in the 13 quarterly reporting States on July 1 were down 8 percent from a year earlier, and the lowest for the date since 1975. Fed cattle marketings in the second quarter were about unchanged from the large level of spring 1985. Second-quarter placements were the smallest for the quarter since 1972.

Feedlots are current in their marketings, and while cattle on feed are down 8 percent, producers expect marketings this summer to decline only 5 percent from last summer. July placements rose 43 percent from last July's record low levels. Cattle on feed on August 1 were down 1 percent from a year ago. This was the second lowest inventory since the series began in 1972.

Cattle continue to remain on pasture longer, and are placed on feed at heavier weights. Marketing weights are expected to remain heavy, although below 1985's record levels. Slaughter weights declined this spring from last year's record. Although feeder cattle supplies are down, there are a high

number of yearlings coming off very good weight gains on grass in most areas. These will continue to support large fed cattle marketings through much of 1987.

Effects of the Dairy Termination Program (DTP) on beef production in second-half 1986 will diminish as dairy cow slaughter declines. Beef production this summer may be about the same as a year ago. However, continued heavy meat purchases for domestic and export use (to offset the impact of increased DTP beef production) will likely reduce beef supplies available for "normal" domestic consumption by 1 to 3 percent, especially with the large export sales to Brazil.

Fourth-quarter production is likely to drop about 5 percent as nonfed slaughter, particularly of dairy cows, drops sharply. Beef cow slaughter has already declined, as forage conditions in most areas are very favorable. If recent rains and cooler temperatures in the Southeast continue, pasture growth for fall and winter grazing should result in further slaughter reductions in this area.

Producers are likely to reduce beef cow culling as stocker-feeder prices

Cattle Inventory on July 1

Class	1984	1985	1986	1986/85
				Percent change
		1,000 head

Milk production

¹Federally inspected slaughter, certified

strengthen. Good-to-excellent grazing conditions in most areas could encourage more fall and over-winter grazing programs, particularly for lighter-weight stocker cattle. In addition, feeders' demand for these cattle will increase as cattle prices rise and grain prices decline. Both these factors increase the price for the reduced supply of feeder cattle.

Beef production is expected to decline about 6 percent in 1987. Fed cattle marketings will remain large, keeping slaughter weights high. All the supply reduction will result from reduced nonfed cattle slaughter, particularly of dairy cows.

However, total red meat and poultry supplies are likely to remain near record levels. Large supplies of rela-

tively lower-priced competing meats, particularly poultry, will hold down price gains for the higher priced beef. Choice fed steers at Omaha may average in the lower- to mid-\$60's next year, while yearling feeder steers average in the mid-to-upper-\$60's. Utility cow prices may average in the low \$40's, as nonfed beef slaughter for hamburger and processed meat products declines. (Ronald Gustafson (202) 786-1830)

•Hogs

The hog-corn price ratio averaged 30 to 1 in July, the highest monthly average since records were established in 1909 and up sharply from June's 22 to 1. Generally, a hog-corn ratio of 22-23 to 1 would cover total costs for an average farrow-to-finish operation. A

higher ratio usually signals an expansion of the breeding herd, leading to increased feed grain consumption and increased pork production 3 to 4 quarters later.

However, the high percentage of sows in early July's total slaughter suggests that producers are not responding immediately to the higher returns or the favorable outlook for the remainder of the year. Current projections are that the hog-corn ratio will exceed the breakeven level for the remainder of 1986 and at least the first half of 1987.

The high percentage of sows in total slaughter may suggest that producers are taking advantage of relatively

high sow prices to generate cash flow, or that some producers are leaving the industry. For example, a sow weighing 470 pounds selling for \$51 per cwt would bring in \$96 more than a gilt weighing 235 pounds at \$61 per cwt.

Hog prices averaged about \$61 per cwt in July and may remain near that level through most of August, when pork production is seasonally low. In September, when production increases seasonally, prices may fall to the mid-\$50's. The high prices are due to a reduced rate of slaughter, low stocks of frozen pork, and lower imports of pork products and live hogs.

Higher poultry production is tempering further hog price gains. Prices are expected to average \$56 to \$60 in the third quarter, then drop slightly as production picks up this fall. In the fourth quarter, prices are expected to average \$53 to \$57 per cwt at the 7 major markets.

Hog prices are projected to average in the low to mid-\$50's in 1987, compared to near \$50 in 1986. Red meat supplies may be moderately lower, strengthening hog prices. However, poultry production is expected to continue its long-term rise, tempering any hog price increases.

Pork imports totaled 526 million pounds, carcass weight, during first-half 1986, down 12 percent from a year ago. Canada, the United States' largest supplier, increased its exports by 17 million or 8 percent. The Canadian dollar was slightly weaker against the U.S. dollar than a year ago during first-half 1986.

The United States' second largest pork supplier, Denmark, reduced its U.S. exports by 68 million pounds, 28 percent. The Danish kroner has appreciated sharply against the dollar in recent months. However, the EC recently increased its export subsidies, which may moderate the decline in exports to the United States.

Live hogs imported from Canada totaled 0.2 million head during January-June 1986, down 72 percent from a year ago. Countervailing duties of \$Can4.386 per cwt were levied last summer. For all of 1986, hogs imported from Canada may total 500,000 to 700,000 head. Recently, hog imports from Canada have climbed because of the sharp rise in U.S. hog prices.

Ratio Of Hog to Corn Prices Now Favors Herd Expansion

Pork exports during the first half of 1986 totaled 44 million pounds, 39 percent below last year. Shipments to Japan are up 67 percent to 22 million pounds, because of lower prices from a declining dollar. Mexico, however, has cut purchases to 2 million from 1985's 24 million [Leland Southard (202) 786-1830]

●Broilers

Broiler meat output from federally inspected plants in second-quarter 1986 was up 4 percent from 1985. Based on the hatch of broiler-type chicks, output in the third quarter may be 4 percent above 1985.

Producers will likely continue to make money during 1986 and into 1987. Third-quarter profits have been very favorable for producers outside areas affected by high temperatures. Feed prices are dropping as new loan rates become effective. Thus, broiler production costs could stay near 1985 levels, and with stronger prices, net returns will improve.

Consequently, fourth-quarter output may expand by 6 percent from 1985. This level would still be below the second-quarter high, so limits on growout capacity will not pose problems. In the first quarter of 1987, producers may expand output by 7 percent from 1986.

The midyear report that pork producers were not expanding production, and the heat and resulting slower

weight gains, helped boost prices early in the third quarter. Prices in the 12 cities during third-quarter 1986 may average 69 to 73 cents per pound, up from 51 last year. Prices are expected to decline seasonally in the fourth quarter and may average 55 to 59 cents per pound, up from 50 last fall.

Declines in red meat production and higher prices in early 1987 than in early 1986, especially in cheaper cuts and hamburger, will likely strengthen broiler prices. However, the expected 7-percent rise in output will likely moderate some of the price gains, and prices may average 51 to 55 cents per pound, up from 50 in 1986.

Broiler exports reached 256 million pounds in first-half 1986, 26 percent above last year. Shipments to Japan were up 52 percent to 69 million pounds because of a stronger yen. Exports to Egypt, at 10 million pounds, were twice last year's mark, and are expected to increase greatly from the Export Enhancement Program. [Allen Baker (202) 786-1830]

●Turkey

Output of turkey meat from federally inspected plants during the third quarter is expected to be 12 percent above 1985. Producers are continuing to place more turkeys for slaughter in the fourth quarter. If they continue to do so, output could be 15 percent above last year.

The demand for turkey, especially processed turkey products, is strong. During first-half 1986, turkey used in further-processed items was up 15 percent from 1985, boosting per capita consumption of turkey outside the fourth quarter. But with reduced supplies of red meats in the remainder of 1986 and in early 1987, even more consumers may turn to processed turkey.

Cold storage stocks of frozen turkey have been above 1985 thus far in 1986. In the second quarter, retailers began building supplies of whole turkey for holiday sales. In the past 2 years, retailers have run low on turkey supplies by Christmas. This year they seem to be stocking up early and thus firming prices.

The strong demand for turkey has meant that prices have not slipped, even with sharp increases in production. In first-half 1986, when production was up 14 percent from 1985, prices for 8- to 16-pound commodity-

Hatchability of Broiler-Type Eggs Down in 1986

Changes in the Milk Production Industry, 1955-1985

Item	1955	1975	1985	Percent change per year (compound annual rate)	
				1955-75	1975-85
No. of cows (mil.)	21.04	11.14	11.03	-3.1	-0.1
No. of farms (thous.)	2,763	444	274	-8.7	-4.7
Cows per farm	8	25	40	5.9	4.8
Pounds per cow per year	5,842	10,360	13,031	2.9	2.3
Total milk production (bil. pounds)	122.9	115.4	143.7	-3	2.2
Milk production value per farm					
Nominal \$	1,755	22,970	67,347	13.7	11.3
1985 \$	7,187	43,267	67,347	9.4	4.5

pack hen turkeys in the Eastern Region averaged 65 cents per pound, down only 2 cents from 1985. During third-quarter 1986, prices may average 78 to 82 cents per pound, up from 78 last year. Prices in the fourth quarter may average 88 to 92 cents per pound, about the same as last year.

Net returns to wholesale turkey producers have been above 1985's positive returns thus far in 1986, and should continue that way. That would mean positive returns since mid-1984, and act as an incentive to expand production again in 1987. Producers are expected to increase first-quarter 1987 production by 20 percent over 1986. This may result in 8- to

16-pound hen turkeys averaging 57 to 63 cents per pound, down from 62 in 1986. [Allen Baker (202) 786-1830]

•Eggs

Based on chick hatch in January-March, producers likely will add more replacement pullets to the laying flocks during third-quarter 1986 than they did in 1985. Producers have been force-molting about the same percentage of old hens as in 1985. Thus, the number of layers will likely be above the 1985 level through the remainder of 1986.

While the rate of lay will likely be about the same, higher numbers of layers are expected to boost egg

production in second-half 1986 about 2 percent from 1985.

Egg prices have been strengthened by concerns over heat-related supply losses, especially early in the third quarter. Prices of Grade A large eggs in New York during the third quarter may average 73 to 77 cents per dozen, up from 68 last year. Fourth-quarter prices may average near 70 cents per dozen, down slightly from 1985's 76 cents. Prices in first-quarter 1987 may average in the mid-60 cent range, down from 74 in 1986. Prices are likely to be lower with continued higher production.

After being in a price-cost squeeze during second-quarter 1986, producers are likely to turn a profit in the fourth quarter and into early 1987. While egg prices may slip, feed costs are also expected to be below 1985 and result in favorable returns. [Allen Baker (202) 786-1830]

•Dairy

Wholesale butter prices started to rise in late June and rose 16 cents per pound by early August. Prices will probably not rise further, because large Government stocks are available at the market price.

By early August, American cheese prices had risen 4 to 6 cents per pound. Some additional increases are likely as the supply-demand balance for milk tightens further.

The wholesale price strength resulted primarily from milk production reductions caused by the DTP, and from continued strong commercial use of milk and dairy products. Commercial stocks were low this spring, and abnormally high temperatures over much of the country have lowered the fat content of milk—further pinching already tight cream supplies.

Wholesale price increases through early August were equivalent to 40-60 cents per cwt of milk. However, only a little of the increase was reflected in July milk prices, because the largest wholesale rises occurred after mid-July. The July Minnesota-Wisconsin (M-W) price for manufacturing-grade milk was \$11.06 per cwt, up 6 cents from June. This increase will be seen in minimum prices for fluid milk during October. The August M-W price will be up from July and the highest since the spring of 1985. This fall's milk and cheese prices probably will be modestly above August levels. [James Miller (202) 786-1830]

Emerging Technology in Milk Production

Emerging technology continues to alter the dairy industry. Milk production per cow has more than doubled since 1955, cutting the number of cows needed. Specialization in dairying, combined with increased output, has resulted in a dramatic decrease in the number of commercial dairy farms. Increased technology would accelerate these trends.

Some technological advances that have boosted production are artificial insemination and improved breeding, better nutrition, automated grain feeding systems, use of higher quality forage, and disease control. Technological advances that have affected the number and size of farms, and industry efficiency, include the milking machine, better housing systems, barn cleaners, silo unloaders, and bulk milk tanks. Improved refrigeration, transportation, and processing technology has also influenced the location, structure (number and size of herds), and efficiency of milk processing and marketing.

New technologies on the horizon are nutritional supplements, biotechnology—including bovine growth hormone (bGH) and embryo transfer, improved environmental management, and microcomputers to assist in feed, financial, and herd management.

Bovine growth hormone could be the biggest technological contribution to date. Bovine somatotropin, as it is technically called, is a naturally occurring protein hormone, produced in the pituitary gland of cattle, that regulates body metabolism and therefore milk production.

Through recent breakthroughs in genetic engineering techniques, the bGH gene can be transferred from animals to ordinary bacteria cells. These bacteria can be reproduced on a large scale at relatively low cost, making the purified product available for commercial use. The process is similar to that used to produce human insulin and interferon.

Bovine growth hormone has not been approved by the Food and Drug Administration (FDA) for commercial use. However, it has been approved for research under controlled conditions, and the sale of milk and meat from

experimental cows injected with bGH has been approved. At present, daily injection is the only effective way of administering bGH. Research is underway to develop a slow-release product or implant.

Injections of bGH increase body metabolism and milk production by raising blood flow through the mammary system. Research has found that under controlled conditions, milk yields increase 10-40 percent within 3 days of initial injection, when administered during the latter two-thirds of a normal 305-day lactation period.

While the optimal time for administering bGH is still being researched, production increases have been greater during middle and late lactation than during early lactation, when milk yields normally tend to be higher. Thus, 10- to 40-percent increases over the latter 215 days of lactation translate to an increase of 7 to 28 percent annually.

A common misconception is that there is a 40-percent increase in milk production during the full lactation period. Another assumption is that essentially all farms will adopt the technology immediately. The incorrect conclusion: one-third fewer milk cows and dairy farms are needed. Such a dramatic impact is unlikely in the 1980's—or in the foreseeable future. FDA has not approved bGH for commercial use, and is not likely to have sufficient data for approval before 1989 or the early 1990's.

Concerns have been raised about the possible effects of bGH on human safety, animal health, and the overall environment. bGH is a species-specific protein and is not biologically active in humans. Also, published research indicates that the product has had no short-term ill effects on animal reproduction, nor does it change the incidence of mastitis or nutritional disease in cows. From an environmental standpoint, the bacteria used to produce the hormone pose no threat because they are able to survive only in a controlled environment.

The largest concerns appear to be how increased milk production will affect prices received by dairy farmers, and if this will have a structural impact on the industry. This concern is especially acute because of chronic excess milk supplies.

Milk Yields Must Increase At Least 5% For bGH Use To Be Profitable

Dollars per cwt

*Average based on 14,000 pound average milk yield, and \$0.25-per-dose cost of bGH.

In the 1950's, dairy farmers were faced with major decisions when bulk-tank technology became popular: Should they remain in dairying? Should they increase the size of their operations? Should they adopt and invest in the associated bundle of capital improvements? These structural changes resulted in fewer and larger dairy herds, requiring increased investment. Also, storage capabilities were expanded and transportation was made easier.

Many questions still remain before the likely effects of bGH on industry structure and performance can be reliably evaluated. Among them are:

- The additional nutrients required to sustain animal health and body condition over multiple lactations;
- The extent to which cows will need more feed when injected with bGH, and what feed ration alterations are needed to furnish the required additional nutrients;
- The long-term impacts of bGH on animal health and productivity;
- The effects of animal stress in high-temperature, high-humidity regions on feed consumption, animal health, and milk production;
- The cost of producing bGH and the commercial cost to dairy farmers;

- The likely adoption rates by region, type, and size of herd;
- Production changes in cows and herds with different genetic bases and different feed and management quality regimens; and
- The type of management needed to effectively run a technologically advanced program.

Farmers with herds of all sizes could easily adopt this technology. General experience and research results indicate, however, that better-managed herds may benefit most, and poorly managed herds may be even further disadvantaged regardless of herd size. This in itself should lead to a more efficient industry.

Profitability of bGH use will likely be the biggest factor in adoption. If bGH injections cost 25 cents a day over a 215-day injection period, and additional feed and other expenses cost \$3.25 per cwt of additional milk output, then from a cow with an annual output of 14,500 pounds, at milk prices of \$12.50 per cwt, a producer would need at least a 6-percent increase in production to cover added costs. Any further output gains would make bGH profitable. Preliminary results suggest gains of at least 10 percent could be reasonably expected.

If bGH is widely adopted it would take fewer cows—and probably fewer dairy farmers—to produce the required milk supply. Since feed efficiency would be increased, fewer resources would be required and costs of milk production would likely fall, resulting in larger supplies and lower prices to both farmers and consumers. Fluid milk and manufactured dairy products would be more competitive with other drinks and foods. The U.S. competitive position in world dairy markets would also be enhanced.

Other countries are also conducting research and field tests on bGH. Failure to adopt this technology could place the U.S. dairy industry at an even further competitive disadvantage. Although short-run structural adjustments may be painful, efficiency-enhancing technology is likely to benefit both well-managed dairy farms and consumers in the long run. *[Richard Fullert and Carolyn Betts (202) 786-1823 and Boyd Buxton (202) 786-1825]*

Acreage Reduction Programs Reducing U.S. Grain* Production—Sort Of

*Grains include wheat and feed grain.
1986/87 forecast.

CROPS OVERVIEW : LOWER PRODUCTION FORECAST FOR MOST CROPS

Total domestic output for most of the ten major field crops will be less this season than in recent years. For most crops, declines resulted from reduced plantings brought about by increased participation in commodity programs.

The season-long drought in the Southeast and, to a lesser extent, the hot, dry weather that developed at midseason in the Delta, Kentucky, and Tennessee, had a severe effect on regional crop production. But for most major field crops, particularly food and feed grains, the regional adverse weather has had a negligible national impact.

Growing conditions were good to excellent through mid-August in the Midwest and Northern Plains, where the bulk of the U.S. corn, soybean, and spring wheat crops is grown. Consequently, above-average production in these regions is offsetting losses due to the drought.

The 1986 winter wheat crop is projected to be down 16 percent from last year, due to a 10-percent drop in harvested acreage and a decline in the average per-acre yield from about 38 to 35.4 bushels. However, a 4-percent jump in other spring wheat plantings and very favorable growing conditions in the Northern Plains point to a near-record 530-million-bushel crop.

Last year, average per-acre yields for three feed grains were record high—118 bushels for corn, 66.7 for grain sorghum, and 63.6 for oats. This season's yields are estimated at 120.4, 63.7, and 58.8 bushels per acre, respectively, and harvestings are expected to fall 8 to 19 percent. Thus, total output is anticipated to drop 6 percent for corn (in spite of a record yield), 23 percent for grain sorghum, and 15 percent for oats from a year ago. Barley production is forecast to rise 10 percent with increased harvestings and a higher yield.

For 1986, 85 percent of the peanut crop, 94 percent of the tobacco crop, and a greater share of the soybean and cotton crops (compared to food and feed grains) is being grown in the drought-affected Southern States. Consequently, the drought has had a relatively greater impact on production of the four major non-grain field crops.

The peanut crop is projected to be down about 14 percent to 3.55 billion pounds, while tobacco will be off 21 percent to 1.2 billion pounds. The soybean crop is estimated to fall about 6 percent to 1.98 billion bushels, with harvested area down 2.3 percent to 60.2 million acres and the average per-acre yield off from a record-high 34.1 bushels last year to about 33 bushels. Due to a 10-percent decline in plantings and a 9-percent drop in per-acre yields from a record 630 pounds to 573, the cotton crop is forecast to fall 21 percent to 10.7 million bales. *[Michael Hanthorn (202) 786-1841]*

CROP HIGHLIGHTS

•Wheat

At an estimated 506 million tons, the 1986/87 world wheat crop will be second only to 1984/85's 516 million tons. The 1986/87 U.S. crop, the smallest since 1979/80, accounts for all of the shortfall while foreign wheat production in 1986/87 is projected at a record. This, coupled with carry-in stocks, means record worldwide wheat supplies for the year.

The 1986 U.S. harvest is estimated at 2.16 billion bushels. Near-record participation in the 1986 acreage reduction program and unfavorable planting conditions in the Soft Red Winter wheat area resulted in a 3.6-million-acre reduction in plantings. The harvested yield is estimated at 33.5 bushels per acre, 2 below 1985 because of the greatly reduced Soft Red yields.

Record carryover will put U.S. supplies at an all-time high 4.07 billion bushels. Projected disappearance will

be up 13 percent from last season because of likely increases in overseas demand. However, at the end of the 1986/87 crop year, carryout will only be slightly smaller than the carryin of 1.9 billion bushels.

Total wheat production for the major foreign exporters (Argentina, Australia, Canada, and the EC-12) is forecast to rise about 5 million tons to 125 million in 1986/87. While adverse weather has depressed expected yields and production in Australia, significant production gains are anticipated in Canada, where large yields are coupled with an estimated 500,000-hectare increase in area. At 14.2 million hectares, the Canadian area is record large. A small part of this increase is likely to have come from reduced barley area, as anticipated barley price declines make wheat relatively more attractive. Similar changes are likely taking place in Australia as well.

Production among the major wheat-importing countries is forecast down

from 218 million tons to 215 million. Lower Soviet production accounts for all of the decline. The USSR's area is forecast about 1 million hectares below last year, and hot, dry weather from April through mid-June has depressed yields. Forecast yield declines translate into production losses of about 7 million tons, or 8 percent, for the year.

In contrast, China's production is estimated at 87.5 million tons, up more than 2 million from last year. A record area and favorable yields are anticipated.

Continued low wheat export prices, along with the decline in Soviet output, are contributing to an anticipated 6-million-ton pickup in global trade (excluding intra-EC trade). This translates into a significant increase in U.S. wheat exports—up by over 6 million tons to over 31.5 million.

Much of the increase will be to various countries in North Africa receiving EEP offers, where total commitments through mid-August are well ahead of a year ago. [James Cole (202) 786-1691 and Allen Schienbein (202) 786-1841]

•Rice

U.S. production is forecast at about 125 million cwt in 1986/87, well below output of the past 2 seasons. A drop in acreage and lower yields are cutting production. According to the latest crop production report, harvested acreage is expected to be down 7 percent from the previous year. The 1986/87 rice program requires producers to idle 35 percent of their base acreage. Over 90 percent of base acreage was enrolled in the program.

¹600-700 lbs. medium no. 2. ²Grade A Large

³No. 1 Yellow. ⁴No. 2 Yellow ⁵No. 1 HRW.

Although production is not expected to increase in 1986/87, a large carryin stock may boost supply to a record 215 million cwt. Even with exports projected to shoot upward by 45 percent, from 55 to 80 million cwt, stocks are likely to remain large. Total use will probably exceed production by 17 to 18 million cwt.

U.S. rice prices have dropped by over 50 percent since the marketing loan went into effect on April 15, and the U.S. share of world exports is forecast to rise from 18 percent in calendar 1986 to 22 percent in 1987. Domestic consumption is expected to increase modestly, as rice consumption in restaurants increases and new grocery store items containing rice are introduced.

Global rice production is forecast at a record 320 million tons (milled basis) for 1986/87, up about 4 million from the year before. The bulk of the increase is in China, the largest producer and a major exporter, where production is expected to be up about 5.5 million tons. Production among several other major producers is also forecast to rise, including Bangladesh, Burma, Indonesia, and Pakistan, whose collective output may increase by almost 2 million tons.

World trade in 1986 is forecast at 12.3 million tons (milled basis), up about 800,000 from last year. Some of the increase results from increased purchases by Brazil and Peru. The pace of Thai shipments had, by June, risen 10 percent above a year earlier. Thai sales are now forecast at 4.2 million tons for the year, up slightly from calendar 1985 and second only to the record 4.5 million in 1984. *[Janet Livezey (202) 786-1840 and James Cole (202) 786-1691]*

●Feed Grains

World coarse grain production in 1986/87 is forecast at 821 million tons, down about 23 million from the previous year. Foreign production will likely fall about 3 million tons, with an 8-million-ton drop in the USSR, but foreign output is still projected near the 1984/85 record of 571 million.

Some production changes are already occurring among coarse grain exporting countries. Production among the major foreign export competitors (Argentina, Australia, Canada, South Africa, and Thailand) in 1986/87 is forecast to fall about 1 million tons to 64 million.

While some Canadian barley area probably shifted to relatively more profitable wheat, expected yield increases will be more than offsetting. A similar shift is taking place in Australia, where the barley area is forecast to fall 700,000 hectares. The absence of price guarantees for barley, while the wheat price remains supported, has been a major factor. However, a return to more normal-trend corn yields in Argentina after a record crop in 1985/86 will be responsible for lower projected output there. Drought lowered yields in Thailand.

Aided by improving economic conditions, reduced energy prices, and lower grain prices, global coarse grain trade is forecast to expand to over 90 million tons (excluding intra-EC trade) in 1986/87, an increase of almost 7.5 million over the previous year. The 1986/87 U.S. market share may increase to 52 percent from the weak 43 percent of a year earlier. *[James Cole (202) 786-1691]*

●Oilseeds

The coming year will be a difficult one for many of the world's oilseed producers. Record 1986/87 world production of oilseeds, meal, and oil, and record or near-record carryin stocks, mean very large world supplies and continued downward pressure on oilseed and product prices. World oilseed and product consumption and trade are likely to show only limited growth, and carryout stocks for most oilseeds and products will increase again.

The drop in 1986/87 U.S. soybean loan rates is expected to be modest, especially compared to the 25-percent-or-more drop for grains. This will limit declines in world soybean and soybean meal prices, and may stimulate expansion of foreign oilseed production.

Foreign soybean production in 1986/87 is expected to rise about 5 million tons to 44 million, and sizable gains are also expected in peanut output. This continues the rapid expansion of the last few years, which has seen foreign oilseed production increase 23 million tons—nearly one-fourth—since 1981/82.

This early production outlook is subject to considerable change, since Southern Hemisphere crops will not even be planted for several months. But the general direction is clear. Given a return to average weather, Brazilian yields will recover from the drought damage of 1985/86. While Brazil's acreage is uncertain, some

Corn Ending Stocks, Including Stocks Under Loan, Projected to Rise

Billion bushels

*Government-held stocks include CCC inventory, FOR, and outstanding loans, including special storage program. 1986/87 forecast.

small gain seems likely because abandonment will be less than last year when weather was poor. Also, recently announced Government prices favor production of corn and edible beans over soybeans.

Paraguay's crop, also damaged by drought in 1985/86, should increase sharply in 1986/87. The expansion of soybean area in Argentina will continue this year. Domestic prices favor oilseeds over wheat, and soybean acreage is expected to increase.

China's push to expand its domestic livestock industry and soybean exports is continuing. Government procurement prices for soybeans have been increased, and farmers have apparently increased acreage by nearly 9 percent. The 1986/87 crop is expected to increase by 1 million tons to a record 11.5 million.

U.S. soybean production in 1986 is forecast to be 1.98 billion bushels. Despite the production decline from last year, U.S. supplies are expected to be about the same because of the record expected carryover of 525 million bushels. Commercial stocks could be tight at about 50 million bushels, with the balance held under Government loan or Government-owned. Loans on 1985-crop soybeans can be extended for 1 year beyond the loan maturity date.

Prices in 1986/87 will likely range between \$4.60 and \$5.00 a bushel. The lower bound is based on the assumption that the Secretary lowers the 1986 loan to the minimum \$4.77 a bushel. The upper bound reflects the likely profitable loan-redemption price for outstanding 1985 crop loans.

U.S. exports are forecast to rise slightly to 760 million bushels in 1986/87 while crush will remain unchanged at 1,055 million. Soybean meal demand will be the prime motivation to crush, since the vegetable oil market will remain in the doldrums. Total U.S. soybean meal demand is expected to be virtually unchanged in 1986/87 from 1985/86. If Brazilian production recovers from 1985/86's drought, U.S. exports of soybean meal will decline, but domestic use is likely to rise because of reduced availability of other protein sources. Prices for soybean meal likely will range between \$130 and \$155 a ton in 1986/87.

Prices for soybean oil will likely weaken in 1986/87. Although U.S. edible oil consumption is expected to post a solid 2.5-percent-plus gain, imported palm oil will depress U.S. domestic soybean oil prices. Prices are expected to range from 13 to 18 cents per pound. *(Frederic Surls (703) 971-0790 and Roger Hoskin (202) 786-1841)*

•Cotton

Despite plunging prices, world cotton production in 1986/87 is expected to fall only 5 percent, from 79 million bales to 75 million. The bulk of the decline will occur in the United States. Foreign production is expected to total nearly 65 million bales, down slightly from 1985/86.

A 3-percent lower area, mostly in the United States, accounts for the small production decline. Foreign area is forecast to show only a 1-percent drop. While some foreign producers are responding to lower prices by reducing area and production, others are making very little adjustment.

Only in Australia is the world price clearly the most important factor leading to less cotton in 1986/87. Australia, which consumes only about one-tenth of its own production and exports the remainder, is forecast to show a 25-percent drop in area and production.

Production in China is expected to rise because of higher yields. Egypt is forecast to produce 2 million bales, the same as in 1985. Production will con-

tinue strong in Chad, Mali, Burkina Faso, and other African nations, where cotton is the only exportable product.

Only slightly lower production is expected in India and Pakistan. Area in both countries is projected to drop by a small margin, but prices continue to favor cotton production. In Pakistan, where the Government is a monopoly buyer, the farm-gate price has been set at the same level as last year. Yields in both countries have been growing rapidly and are expected to remain high this year because of the use of better varieties and improved techniques.

The 1986 U.S. cotton crop is forecast at 10.7 million bales, based on August 1 conditions. Planted acreage of 9.6 million was 10 percent less than 1985. The forecast yield of 573 pounds would be 9 percent below last year's record, but equal to the 5-year average. Abandonment is higher this year because of adverse summer weather in the Southern Plains. U.S. harvested area is expected to be around 8.9 million acres, 13 percent below 1985. The U.S. supply of cotton for 1986/87 is forecast at 20 million bales, nearly 2-1/2 million above 1985/86 and the largest since 1967/68.

Although imports of cotton textiles remained high and cotton prices rose relative to polyester, U.S. mills used more cotton in 1985/86 than at any time since 1979/80. Reasons include a shift in consumer preferences toward natural fibers, and the realization that cotton will become less expensive now that the new farm bill is in effect. Mill use for 1985/86 totaled 6.4 million bales, and may total 6.8 million in 1986/87. The seasonally adjusted annual rate of use was 6.8 million bales in June, a 9-year high. *(Carolyn Whitton 786-1691 and Sam Evans (202) 786-1840)*

•Tobacco

As of August 1, U.S. tobacco output was forecast at 1.2 billion pounds, down 21 percent from last year due to reduced acreage and lower yields. Flue-cured production was forecast at 664 million pounds and burley at 425 million. Flue-cured production is down 17 percent and burley 26 percent from a year earlier.

Flue-cured sales began July 29 in the Georgia-Florida belt. Auction prices averaged 21 cents a pound lower over the first 2 weeks of sales than last year because the price support level is lower and less upper-stalk tobacco was

sold. Price supports have averaged \$1.438 per pound in 1986, compared with an effective support of \$1.65 in 1985. Loan rates range from \$0.96 to \$1.97 per pound. Quality was better than a year ago and growers placed less tobacco under loan. Net returns to growers are averaging about the same as a year ago since the grower assessment has been cut sharply.

Producers are required to contribute 2-1/2 cents per pound of flue-cured tobacco sold in 1986, to cover potential losses (excluding administrative costs) of tobacco placed under loan from the 1982-84 and 1986 crops. Purchasers also are required to contribute 1-1/2 cents per pound to cover potential losses from the 1986 flue-cured crop. The 1986 crop is the first year in which purchasers are required to pay an assessment, as mandated by the Consolidated Omnibus Budget Reconciliation Act of 1985.

The assessment also will be used to offset any required reductions from the statutory loan rate under the Gramm-Rudman-Hollings budget law. Use of the assessment for this purpose may not exceed an amount equal to 1 cent per pound of producer marketings.

Under provisions of the Reconciliation Act, the Commodity Credit Corporation (CCC) acquired 212 million pounds of 1983-crop burley tobacco loan stocks when the loans were called on May 7, 1986. In June, CCC invited bids for purchases and at the end of July, sold 71 million pounds of that crop to successful bidders for \$44.2 million. *(Verner N. Grise (202) 786-1840)*

•Peanuts

The forecast for 1986/87 production is 3.6 billion pounds, 14 percent below last year, even though planted acreage increased slightly. Prolonged drought in the Southeast, the major peanut-producing area, caused the average per-acre yield to fall 14 percent from 1985 to 2,414 pounds. The unusually high temperatures accompanying the drought are expected to reduce crop quality. Crushing of 1985/86-crop peanuts for oil, cake, and meal is running 24 percent ahead of last season.

Carryin stocks for 1986/87 are expected to be less than 1 billion pounds, compared with last season's record 1.4 billion. *(James Schaub (202) 786-1840)*

●Fruits & Vegetables

Part of U.S. agriculture's financial situation is bleak, but fruit and vegetable farmers are thought to be prospering. Prices for most fruits and vegetables have not fallen the way wheat, corn, and soybean prices have. Fresh produce consumption has been growing, and fruit and vegetable farmers are less dependent than grain farmers on the vagaries of export markets.

However, freezes have destroyed parts of the Florida and Texas citrus industries, grape prices have plunged in the face of large supplies and slowing growth in wine demand, and increased import competition has put pressure on domestic sales of processed fruits and vegetables. Are fruit and vegetable growers actually prospering?

Although fruit, berry, vegetable, and tree nut farms make up only 4 percent of all U.S. farms, they generated 14 percent of net cash farm income in 1984. January 1, 1986 cash flow statements, obtained from USDA's 1985 Farm Costs and Returns Survey (FCRS), show that per-farm net cash income, after all expenses, averaged \$12,256 for fruit, berry, and tree nut farms, 38 percent more than the U.S. average.

Net cash income for vegetable farms was \$26,648, over 200 percent above the average farm. The high income for vegetable farms reflects not only positive cash flow for the majority of farms, but also the large proportion of vegetable farms in the over-\$500,000 sales category. Vegetable farms comprised 7 percent of the category according to the 1985 FCRS, compared with an average 2 percent for all types of farms. Net cash income for vegetable farms in the over-\$500,000 sales category was \$384,654, compared with \$194,789 for all farms.

The January 1, 1986 average balance sheets reveal that fruit, berry, and tree nut farms have a lower average debt/asset ratio than the agricultural sector as a whole (.17 compared with .22 to .26). Vegetable farms alone are slightly less solvent, with an average debt/asset ratio of .25, but cash grain farms, by comparison, have a ratio of .31.

More fruit and vegetable farms are in a no-debt position (43 and 44 percent, respectively) than the 40 percent of all farms with no debt. Less than 6 percent of fruit farms are highly leveraged, with debt/asset ratios of over .7,

compared with nearly 9 percent of all farms. By comparison, only 3 percent of cash grain farms are in a no-debt position and 13 percent are highly leveraged.

Both cash flow and balance sheet measures show that fruit and vegetable farms are in better financial condition than cash grain farms. Relatively low dependence on export markets and stable prices have sheltered fruit and vegetable farms' cash flow. Furthermore, fruit and vegetable farms are generally located on the East and West Coasts. Farm-land values have fallen less drastically there than in the Midwest, where cash grain farms are concentrated.

However, both balance sheets and cash flow statements reveal that fruit and vegetable farms are not immune to financial stress. About 10 percent of vegetable farms are highly leveraged, with debt/asset ratios greater than .7. Furthermore, about 42 percent of both fruit and vegetable farms have negative household cash income (farm net cash income plus nonfarm income less living expenses), compared with 45 percent of all farms.

Increasing import competition, and supply-demand imbalances in some fruit and vegetable markets, will continue to create financial pain for some growers, although fruit and vegetable farms remain relatively strong. *[Neil Conklin (202) 786-1766 and David Banker (202) 786-1800]*

●Sugar

More than 488,000 short tons of cane sugar were under loan to CCC on August 1, 6.5 percent below last year at this time. The beet sugar loan picture is the opposite. Last year, beet sugar processors had 276,800 short tons under loan. This year 474,636 tons are under loan, an increase of 71 percent.

Since June 14, a strike has shut down the California and Hawaiian Sugar Company (C&H) refinery in Crockett, California. The Crockett refinery is the world's largest, with capacity to refine around 800,000 short tons a year. Since the strike, C&H has placed 170,000 tons of Hawaiian sugar under CCC loan, compared with no sugar under loan at this time last year. So far the effect of the strike on West Coast sugar prices has been small, because stocks were built up in anticipation.

Over the first half of 1986, HFCS-55 prices in the Chicago West market averaged 19.23 cents a pound, dry weight, down over 3 percent from the same period in 1985. Prices are lower because of both cheaper corn and increased competition among producers to expand sales volume in a slower-growing market.

The Consumer Price Index (CPI) for sugar and sweets averaged 170.8 for the first 6 months of 1986, up 3.4 percent from a year earlier. This is slightly more than the combined index of seven sweetener-containing cereal and bakery products, which rose 3.2 percent. An index of seven other sweetener-containing food products increased 2.2 percent. The rise was held down by a 0.1-percent increase for cola drinks, which was partially the result of lower HFCS prices.

The People's Republic of China will purchase about 160,000 short tons of raw cane sugar held by the CCC in Florida at an average price of 4.75 cents a pound. Given CCC acquisition and storage costs of at least 18 cents a pound, the sale represents an estimated loss of over \$40 million.

CCC still holds about 20,000 tons, raw value, of refined beet sugar in storage in Colorado, and the sale represents about 5 percent of total U.S. private and Government sugar stocks as of March 31, 1986. The sugar will be shipped between January and March of 1987.

The effects of the sale had already been largely discounted by the trade, because the intent to sell the sugar on the world market had been announced previously. The sale represents less than 1 percent of world exports and should have only a small effect on world price. *[David Harvey (202) 786-1769]*

World Agriculture and Trade

ARGENTINE EXPORT OUTLOOK UNCERTAIN

Argentina is the world's second largest exporter of grains, oilseeds, and oilseed products, and has the potential to increase its share even further. Its grain and oilseed exports have increased 50 percent since the mid-1970's. If taxes on agricultural exports are eliminated and investments in the marketing infrastructure are increased, Argentina could increase its exports 40 percent by 1990, to 40 million tons. However, low world grain prices could dampen increases.

Traditionally, Argentina has subsidized industrial development by taxing the agricultural sector. But despite subsidies and protective tariffs, most state-run industries continue to run deficits, while agriculture continues expanding.

Investments in farm production and the grain exporting infrastructure could spur exports, and increased exports could help solve the country's economic predicament. Argentina's \$US50-billion foreign debt is equivalent to 70 percent of gross domestic product (GDP). Interest on the debt is equivalent to nearly 50 percent of export earnings, or nearly 100 percent of the balance-of-payments surplus.

The agricultural sector accounts for 15 percent of Argentina's GDP, and the grain handling and transportation

infrastructure accounts for an additional 10 percent. Agricultural exports account for 80 percent of foreign currency earnings, and taxes on agricultural exports generate 20 percent of central Government revenues.

The Government is making agricultural reforms. Farm input prices are being reduced and prices paid for farm products increased. On the other hand, the outlook for lower world prices is already dampening ambitious Government projections for production and export.

New Tax System May Spur Production

High export taxes are levied on Argentine agricultural products. Since prices for traded commodities are set in world markets, the tax burden falls on farmers.

In 1986 the World Bank approved a \$350 million loan for Argentina's agricultural sector. The loan is designed to help the Government of Argentina (GOA) make the transition from agricultural export taxes to a land-based tax system. This may spur crop production by raising Argentine crop prices and forcing idle lands and pastures into cultivation, and by increasing the use of farm inputs and capital equipment.

A land-based tax system tends to encourage marginal increases in farm output, since per-unit taxes will dimin-

ish as output increases. Conversely, export taxes tend to dampen marginal increases, since per-unit taxes are constant.

Marketing Costs Discourage Argentine Production

High marketing margins, resulting from a costly and inefficient grain handling and transportation infrastructure, further depress farm prices in Argentina. Moreover, the grain export sector is already operating near capacity at 30 million tons annually. So, export expansion will require investments in the export-marketing infrastructure.

Almost all Argentine grain is produced within 200 miles of export terminals. Yet marketing costs are about the same as in the United States, where grain is moved as much as 1,500-1,700 miles to port. It is estimated that Argentine farmers receive about 50 percent of the c.i.f. Rotterdam price, while U.S. farmers receive about 75 percent.

Argentina's grain storage capacity may be the most limiting factor in export marketing. Storage capacity has increased from about 15 million tons in the early 1980's to nearly 30 million tons, but storage capacity is still less than 70 percent of average annual production.

This is significantly less than other major exporting nations. U.S. storage

capacity is about 200 percent of annual production (excluding carryover), Canada's at least 150 percent, and Australia's about 120 percent. Argentina's limited storage forces it to sell its grain rapidly, and given seasonal world market conditions, Argentina must offer significant price discounts because grain cannot be stored while farmers wait for prices to rise.

Argentina Has Great Production Potential

Argentine agricultural resources are underutilized, so area and yield are not limiting factors for the expansion of farm production. In crop rotation practices and other cost-saving, conservation-type technologies, Argentine farmers are very sophisticated. But in terms of fertilizer use and farm machinery, Argentine farmers have the lowest technology level among the major grain exporters. This is due to low farm-gate prices and high input prices. High input prices result from import tariffs and value-added taxes.

Historically, Argentine fertilizer prices were high. Despite a drop, only 20 percent of the wheat area is fertilized, compared to 75 percent in the United States. Yields are surprisingly good, though, at nearly 2 tons per hectare compared with 2.5 in the United States. Import tariffs also increase the price of farm machinery. Consequently, many farms are undercapitalized, with planting and harvesting usually contracted out to custom operators. Argentine farmers would enjoy significant

yield increases with increased fertilizer use. In addition, area cropped would expand if machinery use grew.

**Investments Are Critical
for Export Expansion**

Considering both potential yield gains and expansion of area, Argentine agricultural production could grow from its current 40 million tons annually to 50 million by 1990, given favorable crop prices. However, Argentina's grain-exporting infrastructure is already operating at full capacity, so export and production gains will depend on future investment in export facilities. Capital flight and foreign debt servicing have depleted Argentina's investment capital, so most of the required investment in the marketing infrastructure will need to come from overseas lenders, who may be reluctant to make additional loans.

In addition, the global price outlook for grains is depressed this year and likely to remain so in the next few years, as U.S. farm legislation sharply cuts U.S. support prices in the 1986/87 marketing year, with domestic, cash, and export prices following down. (Jorge Hazera (202) 786-1662)

**BRAZILIAN POLICY SHIFTS
SUPPORTED BY U.S. FARM ACT**

Changes in Brazilian agricultural policy favor increased stock holding and are shifting Government incentives away from export crops. In early 1985, a populist democratic coalition replaced an elitist military government. The new government is giving higher priority to the interests of small farmers and consumers. Farmers producing export crops, especially soybeans, are more often large and wealthy, while those who produce crops for domestic consumption, such as corn or dry edible beans, tend to be smaller.

Because of strong domestic economic growth since 1984, a vastly improved balance of payments, and 1986 monetary reforms that reduced inflation from over 200 percent per year to close to 20 percent, Brazil can make agricultural reform effective. Strong domestic demand for food resulted from economic growth, but with prices frozen as part of the anti-inflation campaign, shortages developed. Thus, the Brazilian Government is now beginning to build stocks.

The U.S. farm bill helps the Brazilian Government do this by letting U.S. export prices fall to world market prices. Also, world prices for food grains have fallen below Brazilian prices, allowing domestic sale of imported corn and rice without subsidies.

The shifting of incentives away from export crops is aided by Brazil's great improvement in its balance of payments. This has been made possible by international interest rate declines, debt rescheduling at a reduced risk premium, more favorable exchange rates, and trade surpluses. Brazil's current account balance went from a deficit of \$14.8 billion in 1982 to a surplus of \$0.5 billion in 1984. Exports grew from \$20 billion in 1980 to \$27 billion in 1984. Meanwhile, imports fell from \$23 billion to less than \$14 billion.

**New Policies Affecting
Soybean Production**

The refocusing of Government support away from exports will most affect soybeans, the major field crop grown primarily for export. Soybeans and soybean products were 26 percent of agricultural exports and 10 percent of total exports in 1985, a year of record harvest. Brazilian soybeans and

products are important in world markets; Brazil is the world's largest exporter of soybean meal and soybean oil.

The Brazilian Government is using several agricultural policies to encourage farmers to move away from soybeans into domestic food crops. These policies encompass land reform, research and extension programs, credit, and price supports.

The land reform program, announced in May 1985, plans to settle 1.4 million landless rural families by 1989 by redistributing underutilized land to them. This has received so much publicity and widespread support, especially from the church, that the Government has little choice but to proceed with redistribution. Soybean land is unlikely to be redistributed because it is not considered underutilized. The new farmers will likely grow food crops.

Brazil's extension and research programs have focused on soybeans, and yields have improved. On the other hand, dry edible bean yields have declined over the last 15 years. Dry edible beans have the third largest acreage of any crop grown in Brazil.

The new Government has reorganized the research and extension programs to focus on food crops instead of soybeans. Clearly, research changes will have more long-term effects. But the small, poor farmer has not traditionally received significant extension

**Yield Trends Reflect Brazilian Extension
and Research Emphasis on Soybeans**

assistance, so the reorientation of extension services may have quicker results.

Brazil extends loans to farmers based on cost of production. The program has been altered to allow a smaller percentage of soybean production costs to be financed. Moreover, large farmers are not allowed to finance as large a share of their expenses as small farmers are. This reduces the availability of cheap financing for soybean farmers. Marketing loans have similarly been altered to favor domestic food crops.

The Brazilian price support program has become more important for soybeans, because world prices have fallen. Although the support price is low, \$4.13 per bushel for the 1986 crop, it is above market price in the northwestern producing areas, where transport costs are high. The present policy of delaying price support payments to large farmers, and the continuation of the same low support price for the next crop, should effectively discourage plantings.

Internal Prices Will Favor Grain Over Soybeans

The structure of the Brazilian agricultural markets may provide a stronger lever to move farmers out of soybeans. Although more corn is harvested in Brazil than soybeans, the amount of corn traded internationally is limited, and the Government controls and restricts the quantity traded. Because there is so little international trade, Brazilian prices for corn, rice, dry edible beans, manioc, and other staples are not closely linked to world prices.

Therefore, the decline in world grain prices is unlikely to show up in Brazil. But soybean prices are transferred directly from the world market to the Brazilian market, and lower world prices may discourage Brazilian production.

Soybean Area Momentum

Other factors may offset the price and policy changes. The land reform program gives large owners with underutilized arable land a strong incentive to bring it into production before it gets taken over by the Government. Moreover, the economic reforms that have reduced inflation have made investment in agriculture more attractive than speculative financial investments.

More importantly, soybeans are often the most profitable crop for the large owner. Not only do large farmers often own the needed assets, but in center-west Brazil, the area of agricultural expansion, the erratic rainfall pattern favors soybeans as a less risky crop. The flowering period of soybeans is flexible, so if a dry period occurs during flowering, it has much less effect as long as the rains return. Grains flower at a determined time, so if there is a dry spell at that time, yields are greatly reduced.

Research has given Brazilian farmers a number of soybean varieties well suited to their soils and growing conditions. Soybean yields in Brazil are high relative to alternative crops. Moreover, large soybean farmers have informal channels in the banking system that give them access to commercial and subsidized credit. It will be difficult to actually redirect subsidies to less organized, more poorly connected farmers.

The expansion of soybean area in center-west Brazil will likely continue despite Government policy changes

and low soybean prices. However, in the southern producing areas, including the largest soybean-producing state, Rio Grande do Sul, soybean farms are smaller, and grain yields are more competitive with soybean yields. In these areas, hundreds of thousands of hectares are likely to shift out of soybeans into crops for domestic consumption.

The decline in the southern area should offset the expansion in the west, leaving soybean area little changed despite expanded total crop area. However, if world soybean prices do not decline, Brazilian soybean area will likely expand.

Brazil's actions may result in its losing some of its share of the world market in soybeans and products. However, the loss in soybean exports will probably be offset by higher food-crop production, resulting in smaller grain imports. [Ed Allen (202) 786-1664]

Farm Finance Update

OUTLOOK FOR 1986

Net cash income for the farm sector in 1986 is forecast at \$43 to \$47 billion, little changed from 1985. In real terms, net cash income could fall slightly from 1985. Crop farms are expected to account for 55 to 60 percent of income, down from 62 percent in 1985. Much of the strength in crop-farm net cash income will be derived from direct Government payments and CCC price-support loans.

Net farm income will likely be between \$25 and \$29 billion. Overall, the farm sector's contribution to the Gross National Product will be smaller in 1986, largely because of reduced crop output.

Government Outlays To Be Record Large

Government payments and declining production expenses are the two most important elements of the 1986 farm income forecast. Calendar year 1986 Government outlays to the farm sector will likely reach unprecedented levels, as direct payments total a record \$10 to \$13 billion and net CCC loans add another \$8 to \$12 billion. In 1985, outlays totaled nearly \$22 billion for the three major components which directly impact gross farm income (direct payments including all deficiency and diversion programs, net CCC loans, and purchases of dairy products under the dairy price support program).

Why are Government outlays so high? There are several reasons:

- Market prices near or below loan rates are making participation in farm programs a virtual necessity for financial survival.
- Lower loan rates, with target prices unchanged from 1985, are raising 1986-crop deficiency payment rates, resulting in record payments.
- Advancement of over \$3 billion (through June) in 1986-crop deficiency payments for crops such as corn, cotton, and rice, which normally would have been disbursed in calendar 1987.
- The addition of new programs, such as the dairy herd buyout and conservation reserve programs, which will increase outlays this calendar year. The conservation reserve will add much more in upcoming years.
- Increased use of CCC loans in lieu of open market sales. Forfeitures of these loans also leave the CCC with rising inventory carrying costs.
- With rising outlays, the interest owed to the U.S. Treasury on the CCC's borrowed capital (also considered an outlay) increases.

Most Expense Items To Fall

One of the key developments in 1986 is the 4- to 6-percent decline expected for farm production expenses. Cash expenses fell \$3.5 billion in 1985, and are expected to decline another \$4 to \$8 billion in 1986 because of lower input prices and reduced input use. This puts current-dollar cash expenses at the 1980 level. Cash grain and cattle, hog, and sheep farms, which experienced the largest 1984-1985 cash expenditure declines, will likely see further declines relative to other farm types.

If the 6-percent drop in expenses is realized, it would be the largest annual cut since 1932's 19 percent. The recent cut has maintained the farm sector's net income, since the growth in direct Government payments has not fully offset the decline in crop cash receipts.

Savings of \$1 to \$3 billion in 1986 expenses were initially forecast, due mostly to reduced input use. However, the outlook was changed significantly this spring by:

- the large and rapid decline in fuel prices,
- the spillover effect of the drop in energy prices on fertilizer and chemical prices,

8/01/86 r = revised. Totals may not add due to rounding.

- the absence of increases in the prices of most other less-energy-intensive inputs such as machinery and building materials, and
- lower-than-expected market interest rates and outstanding debt.

Declines of about a tenth are anticipated for energy-intensive manufactured inputs and interest expenses. Lesser decreases are expected for farm-origin inputs, capital repair, and animal health costs. Interest expenses are expected to fall because of a 6- to 8-percent drop in the average interest rate on outstanding debt, and a 3- to 5-percent decline in average outstanding debt.

Livestock Receipts Forecast Up

Crop cash receipts are expected to fall \$7 to \$11 billion to \$61 to \$65 billion. Farmers are again expected to place large quantities of grain and cotton under CCC loan. Total crop output is expected to decline 5 percent, mostly because of lower harvested acreage for program commodities. Average prices received by farmers for crops are forecast to decline 8 to 12 percent, with program commodities such as corn and cotton contributing most of the downward influence.

Livestock cash receipts are expected to rise slightly from the \$69.4 billion of 1985 to \$69-\$73 billion. Livestock marketing volume is expected to remain near 1985, as record or near-record production of milk and poultry products offsets declining red-meat animal output. Prices received for livestock and products are expected to rise slightly from 1985, as stronger hog and poultry prices outweigh reduced milk prices. Cash receipts for poultry and eggs are expected to rise more than a tenth, likely surpassing the record of 1984, when avian influenza caused poultry and egg prices to increase substantially.

1985 Estimates Completed

The first estimates of aggregate 1985 U.S. farm income and balance sheet statistics based on survey data indicate that higher crop cash receipts, continued strong Government payments, and declining cash expenses led to an increase in net cash income of roughly \$5 billion, to a record \$44.1 billion (table 31). Net farm income in 1985 totaled \$30.4 billion, down from \$32.7 billion in 1984. *[Gary Lucier and Richard Kold (202) 786-1809]*

STATES SURVEY FARM FINANCIAL CONDITIONS

Results of a January 1986 survey conducted by the Midwest Association of State Departments of Agriculture in nine States (Illinois, Iowa, Kansas, Michigan, Missouri, Nebraska, North Dakota, Ohio, and Wisconsin) suggest:

- There will likely not be an unusually large exodus from farming in 1986. Five percent of the farm operators in the survey area were not planning to farm in 1986. In a normal year, 4-5 percent of operators cease farming for a variety of financial and personal reasons. The rates ranged from 3 percent in North Dakota to 6.4 percent in Nebraska.
- Financial problems were not indicated as the main reason for most farmers for ceasing operation. Six percent of Missouri farmers plan to leave farming in 1986, but health,

retirement, and other personal reasons, not financial difficulties, were identified as the major forces in deciding to quit. In Ohio, 5 percent plan to cease operations, but only 2 percent for financial reasons.

- Financial problems had a greater effect on family-size commercial farms. Financial problems were the cause of planned departure of 5 percent of Missouri farmers with sales between \$40,000 and \$100,000. Only 1 percent of the farmers in this sales class are quitting for any other reason (retirement). Five percent of Ohio farm operations with sales between \$40,000 and \$100,000 plan to quit, 3 percent for financial reasons.
- The incidence of operators quitting varies widely within States, among areas (Crop Reporting Districts—CRD's), farm types, and sales classes. While 5 percent of Illinois operators expected to quit in 1986, within the State the percentage

Reconciliation of Total Farm Production Expenses and Cash Expenses

Year	Total production expenses	Less operator dwelling expenses					Less capital consumption	Less labor perks	Equals total cash expenses.
		Interest	Taxes	Repairs	Insurance	Total			
Million dollars									
1980	133,138	624	284	413	669	1,990	21,474	579	109,095
1981	139,444	746	304	293	729	2,072	23,573	555	113,244
1982	140,654	848	317	355	859	2,379	23,886	637	113,753
1983	139,468	868	315	223	915	2,320	23,490	616	113,040
1984	141,712	854	319	356	925	2,454	23,020	653	115,585
1985	136,108	769	309	299	910	2,287	21,101	589	112,131

1/ The category "cash expenses" is largely an accounting concept, while "total production expenses" is a broader measure incorporating costs associated with maintenance of the farm household and hired labor.

Farming Intentions and Loan Delinquencies, January 1986*

State	Operators ex- pecting to quit in 1986	Delinquent on principal and/or interest	
		Real estate loans	Non-real estate loans
Percent			
Illinois	5.0	11.6	14.3
Iowa	4.9	11.9	14.5
Kansas	5.6	7.9	8.7
Michigan	4.3	5.0	8.0
Missouri	6.0	10.0	10.0
Nebraska	6.4	8.2	9.7
North Dakota	3.0	8.6	8.7
Ohio	5.0	4.0	5.0
Wisconsin	4.4	3.2	12.3
Arkansas	3.0	8.4	6.4

*Based on Farm Finance Surveys conducted in various States.

ranged from 11 percent in the Southeast CRD to less than 1 percent in the East Southeast CRD.

Only 4.4 percent of Wisconsin farmers expect to cease operations in 1986, but this includes 12.5 percent of the fruit and vegetable growers and 7.1 percent of those with sales less than \$40,000. In Kansas, 5.6 percent of all operators plan to quit, including 10.3 percent of swine producers and 20.0 percent of operations less than 10 acres. But only 3.7 percent of farms greater than 2,000 acres, and 1.6 percent of those with sales greater than \$250,000, plan to exit farming.

- Current loan delinquency problems are large but many delinquent operators plan to continue farming. In Nebraska, 6.4 percent of all farmers expect to quit in 1986, and principal and/or interest payment delinquency

rates are 8.2 percent on real estate debt and 9.7 percent on non-real estate debt.

In Nebraska's Southeast CRD, 14.0 percent of the farmers expect to quit, but delinquency rates are only 7 percent on real estate debt and 6.0 percent on non-real estate debt. In the Central CRD, only 1.4 percent intend to cease operations, but the delinquency rates are much higher—12.2 percent and 14.9 percent.

- Current loan delinquency problems do affect the length of time operators expect to continue farming. In response to "If current trends in income and expenses continue, how long will you be able to farm?", 11 percent of North Dakota farmers felt they could not make it past 1987. Almost 61 percent of these are delinquent on loan payments.

Of the 38 percent who said they could farm for 2-5 years, 22 percent are delinquent; of the 8 percent lasting 6-10 years, 9 percent are delinquent; and of the 43 percent of North Dakota farmers anticipating operating until retirement, less than 3 percent are currently delinquent.

- Lack of adequate off-farm employment opportunities may be contributing to operators remaining in farming. Almost 25 percent of Nebraska operators' income is from non-farm sources (largely financial assets), and 82 percent believe that adequate off-farm income opportunities do not exist. Of those Michigan farmers who expect to quit within the next 2 years, half were uncertain as to their future. Sixty-three percent expressed the need for some form of personal, job, or educational assistance.

The vast majority of farmers appear to be intent on remaining in farming in spite of any current financial problems. The incidence of exit varies widely within States, depending on geographic area, farm type, size, sales volume, and age of operator. Variation is less evident between States. Current loan delinquency problems may have improved slightly, but apparently not enough to buoy expectations of continuing operations. Farmers with current financial problems are wary of a continuation of present trends in income and expenses. [Jim Ryan (202) 786-1802]

SURVEY ANALYSIS: CASH FLOWS AND LEVERAGE POSITIONS

Data obtained from approximately 13,000 survey respondents in the U.S. Department of Agriculture's Farm Cost and Returns Survey (FCRS) indicate that over 55 percent of all farms had positive cash flows in 1985, compared with 49 percent in 1984.¹ The improvement is partially due to a shift in marketing patterns. It appears that substantial marketings, scheduled for early 1986, were shifted to CCC placements in late 1985.

However, overall leverage positions worsened. Debt/asset ratios were greater than .4 on 21 percent of all farms, compared with 19 percent in 1984. The percentage of debt held by these highly leveraged farms increased from 62 percent to 66 percent. Nevertheless, it appears that much of the farm sector is not experiencing financial stress. Nearly 40 percent of all farms were debt-free on January 1, 1986, and another 39 percent had debt/asset ratios less than .4.

The proportion of farms in the most vulnerable financial position—negative cash flows and debt/asset ratios greater than .4—decreased during 1985 from 12.6 percent to 11.2 percent of all farms. Operator debt held by these units declined from 45 percent to 37 percent of total debt. This suggests an improvement in the condition of farms with the most serious financial problems, although a less optimistic interpretation is that many problem farms shut down during 1985.

A farm operation is technically insolvent when its debt/asset ratio is greater than 1.0, that is, its outstanding debt is greater than the value of its assets. Less than 4 percent of all farms were in this extremely vulnerable position as 1986 began, but two-thirds of these had financial difficulties compounded by negative cash flows during 1985.

Condition by Size

¹As measured here, net cash flow is the balance remaining after all cash obligations, including interest, principal payments, and family living allowance, have been deducted from total income from all farm and nonfarm sources.

Failed Commercial Banks

COMMERCIAL BANK FAILURES RISING

The Federal Deposit Insurance Corporation (FDIC) now forecasts 140-160 bank failures during 1986. Banks in Texas, Oklahoma, Louisiana, Colorado, and Kansas are considered the most vulnerable because of their loans to firms in the declining oil and gas industries. Failed banks in these five States accounted for 43 percent of 1986 failures through June 30.

A broader view of the financial problems faced by banks reveals that 39 (60 percent) of the banks that failed in the first half were headquartered in States that are net energy exporters. These 14 States also experienced 21 of the 38 rural bank failures and 46 percent of the agricultural bank failures. While most rural and agricultural banks do not have large energy loan portfolios, depressed economic conditions in areas dependent on oil and gas production place considerable stress on these institutions.

The failure of First Oklahoma on July 14 (the second largest insured bank failure), was attributed to the declining quality of its energy and real-estate loans. While not an agricultural bank, its agricultural loans (about 12 percent of its \$1.1-billion loan portfolio on March 31, 1986) were greater than the total assets of most agricultural banks.

Many other large energy banks also have substantial volumes of farm loans outstanding. Bank holding companies in Texas, Oklahoma, and Louisiana with more than \$1 billion in assets had only 2 percent of their loans supporting farm activity on average, but accounted for \$1.09 billion of farm loans as of June 30, 1985. While these banks are not all overburdened with poor energy loans, they are in the three States which contain the majority of "energy" banks identified by bank regulators. Failures of such banks in the Southwest would have

	Total 1/	Agricultural 2/	Rural 3/

1986 First half	65	28	38

1/ Totals exclude mutual savings banks, savings and loan associations, commercial banks not insured by the FDIC, and banks headquartered in U.S. possessions and territories. Failures for 1986 are as of June 30. 2/ Agricultural banks are those for which the ratio of farm (both production and real estate) loans to total loans exceeded the average of such ratios at all banks in December of the year preceding failure. Agricultural bank classifications for 1986 are preliminary. 3/ A failed bank is classified as rural if its headquarters was located in a nonmetropolitan county. There are about 7,900 rural banks, and 5,000 agricultural banks, of which roughly 4,500 were also rural. There are approximately 14,000 banks in the United States.

negative implications for credit availability in rural and farm communities.

Although most failed rural and agricultural banks are relatively small and reopen under new management, bank failures can have adverse effects on local credit availability. Debtors with troubled loans held by failed banks are probably hurt the most. No bank, including the acquiring bank, will freely buy such loans; the FDIC is often left to administer them. The FDIC tends to be strict with problem debtors since its legal responsibilities are to the failed banks' depositors, bondholders, and stockholders. Agricul-

tural loans totaling \$460 million were held by banks that failed in 1985.

Marginally qualified borrowers in a community where a bank has just failed may also find it difficult to secure credit if the community has few other lending institutions. While replacing failed banks with healthy banks is beneficial, many of these acquiring banks appear to be more risk-averse than the failed institutions, and may make fewer local loans. Moreover, when a local bank fails, the remaining banks may extend less credit, so that their liquidity positions are improved and they appear safer. (Gregory Gajewski (202) 786-1884)

\$500,000 had debt/asset ratios greater than .4, compared with 21 percent of all farms. Over 52 percent of these farms had negative cash flows in 1985. Almost 6.7 percent were technically insolvent compared with 3.9 percent of all farms, and over two-thirds of these large insolvent farms experienced negative cash flows. Family-size commercial farms account for 38 percent of all farms, but are carrying 66 percent of the debt.

Farms with sales greater than \$500,000 account for 2 percent of all farms, and include a large proportion of high-value specialty crop producers. While over 68 percent of these farms are highly leveraged, only 26 percent reported negative cash balances, suggesting that most of these large farms generate sufficient income to service high debt loads. Almost 19 percent of all farm debt is held by these farms.

Farms with sales less than \$40,000 tend to have larger income from non-farm sources which may offset farm losses. Over 50 percent of these opera-

tions reported negative cash balances. These units account for almost 60 percent of all farms, and owe less than 16 percent of all debt. A higher proportion of these operations have little or no debt.

Condition by Type of Farm

Cash grain farmers were the most indebted operators, carrying 37.3 percent of all farm debt into 1986. But these farmers seemed to have sufficient earnings to meet all expenses, as less than 38 percent reported negative cash balances.

General livestock farms were the next most heavily indebted group, owing 26.6 percent of all debt. Over 48 percent of general livestock producers failed to generate positive cash balances.

Field crop (cotton/tobacco) farmers had the largest proportion of producers in cash flow difficulty, as over 53 percent had negative cash balances. Less than 21 percent of nursery producers had negative cash balances.

Condition by Region

The Corn Belt is the most heavily indebted region of the country, carrying 23.6 percent of all farm debt. Farms in the Midwest as a whole (Corn Belt, Lake States, and Northern Plains) hold almost 54 percent of all debt owed by U.S. farm operators. These regions have suffered the greatest land value depreciation in recent years, but relatively fewer of these farms reported negative cash balances, suggesting that many have been able to service their higher debt loads. A continuation of heavy Government support for commodities produced in this region may be necessary for the next few years.

Agricultural Credit Prospects

Highly leveraged farms are at considerable risk, and the potential impact of their inability to meet financial obligations could be devastating for lenders. The distribution of lender-held debt by borrowers' leverage suggests that most lenders' portfolios are at some risk. Over 84 percent of Farmers Home Administration (FmHA) debt is held by farmers with debt/asset ratios greater than .4, with over 35 percent held by technically insolvent operations.

The Farm Credit System (Federal Land Banks and Production Credit Associations) appears to be at less immediate risk than private-sector lenders. Less than 11 percent of combined FLB/PCA debt is held by technically insolvent operations. However, over 65 percent of Farm Credit debt is owed by borrowers with debt/asset ratios greater than .4, suggesting potential repayment problems in the future.

As the Farm Credit System has reduced outstanding loans, it has experienced a decrease in market share, from 35.3 percent of all non-CCC debt to 32.3 percent over the 1985 calendar year. Simultaneously, FmHA share increased from 13.7 percent to 16.2 percent.

Commercial banks appear to be at a slightly greater risk than the Farm Credit System. The commercial-bank share of debt increased from 28.6 percent to 29.6 percent. Bank reports support this survey finding, suggesting that banks are lending to former PCA borrowers and requiring real estate as collateral for short-term loans.

Generally, it appears lenders are continuing to impose credit restraints on borrowers, encouraging debt reduction and further contraction of farm businesses. Credit denial by private lenders has increased the role of the Farmers Home Administration in providing financing for those unable to obtain it elsewhere.

While 1985 was a relatively high-income year for agriculture, the farm sector is still experiencing much financial stress. Family-size commercial farms, particularly cash grain and general livestock farms in the Lake States, Corn Belt, and Northern Plains, have experienced an erosion of asset values. This exposes these farms, and the institutions that provide them credit, to an increasing level of risk.

CCC commodity loans and direct payments have allowed these producers to maintain a cash flow adequate for their obligations. Continued Federal involvement is likely as the sector adjusts to lower commodity prices and further declines in asset values. [Jim Ryan (202) 786-1802]

General Economy

Two major factors have set the stage for faster economic growth in 1986: a declining dollar and falling interest rates.

By the end of 1985, the dollar had fallen 20 percent against a basket of currencies, and against some individual currencies the decline was even more dramatic. The declines tended to make imported goods more expensive to U.S. consumers, while making U.S. goods less expensive to foreigners. The result should have

Trade Balance Response To Dollar Devaluation May Actually Occur 2 to 4 Quarters Later than Forecast*

*Response, known as "J curve," traces out theoretical path of trade balance following a currency devaluation.

been falling imports and rising exports, which in turn should have spurred U.S. production and employment.

The main effect of the depreciation of the dollar was expected about 4 to 6 quarters after the initial decline. Between the time consumers responded to the price signals and the dollar's initial fall, it was expected that the nominal trade balance would continue to worsen. This effect, known as the "J curve," arises because consumption patterns take time to change. For a time, U.S. consumers buy higher priced imports while foreign consumers have yet to discover lower priced U.S. exports. The J curve traces the path of the trade balance after a decline in the dollar.

Using this analysis, a dollar decline beginning in February 1985 should have been felt in trade volumes in the first half of 1986, speeding up 1986 growth and sparking gains in employment and overall production.

The interest rate picture brightened considerably in 1985. Three-month Treasury bills reached a peak for 1985 in March (8.6 percent), and then declined to 7 percent by year's end. Aaa-rated corporate bonds peaked in March (12.6 percent) and then declined to 10.2 in December. Mortgage rates declined continuously through 1985, starting the year near 12.2 percent and finishing at 10.9 percent.

Lower interest rates usually mean an upswing in interest-sensitive areas of the economy: business spending on plant and equipment, business inventory accumulation, consumer purchases of durables such as automobiles and furniture, and consumer purchases of new homes. An upswing in these areas usually leads to a general increase in production and employment.

First Half of 1986 Was Disappointing

The first half of 1986 simply did not conform to the pattern most analysts expected. Industrial production declined 1.8 percent, while capacity utilization declined 2.6 percentage points. These declines represented the first 6-month declines since late 1982, the trough of the last recession. Employment grew slowly through

THE TOKYO SUMMIT: A MANAGED FLOAT AND U.S. AGRICULTURAL EXPORTS

At the Tokyo summit in May 1986, the Group of Seven major industrialized countries (United States, United Kingdom, Japan, West Germany, France, Canada, and Italy) issued a statement which contains the expressed goal of developing policies to reduce the volatility of exchange rates. There are, however, many uncertainties and problems to be faced before a new, "managed" flexible exchange rate system is in place.

Implications for Agriculture

Greater exchange rate stability would benefit trade-dependent sectors of the economy, such as agriculture. Now, in an effort to reduce the risk from fluctuating exchange rates, countries are increasing their food self-sufficiency and/or expanding exports to gain foreign exchange. Once the risk from changes in foreign exchange values is lessened, trade could become increasingly specialized, and agricultural imports should rise. As long as the United States holds a long-term comparative advantage in agriculture, an increase in world commodity trade will be beneficial.

Problems with the Flexible System

A flexible exchange rate system allows countries to pursue domestic monetary and fiscal policies independent of international considerations. However, these changes can cause large movements in exchange rates.

Under the current flexible regime, if the Federal Reserve pursues a tight monetary policy, the slower rate of growth in the money supply tends to cause real interest rates to rise. This attracts investors to U.S. or Eurodollar money-market instruments, causing the dollar to appreciate.

A stronger dollar makes U.S. exports more expensive to other countries, thereby reducing demand. The price of imports into the United States will decline in dollar terms, pressuring domestic industries that compete with foreign goods to lower their prices. Thus, monetary authorities can reduce inflation under flexible exchange rates, but the trade sector bears the short-term burden of adjustment.

Prospects for a Managed Float

As envisioned by Treasury Secretary Baker, the increased coordination by the Group of Seven would work as follows:

1. They will agree to use standard indicators such as rates of exchange, real growth, inflation, unemployment, interest, and monetary growth; and levels of foreign currency reserves, current account balances, and fiscal deficits, to assess country goals and measure economic performance.
2. Each participating country will set forth its economic objectives and forecasts in terms of these measures.

3. The Group of Seven, along with the managing director of the IMF, will review forecast objectives for domestic and international consistency.
4. If significant deviations from planned performance occur, the Group of Seven will try to reach agreement on appropriate actions, focusing on policy fundamentals.

Although in principle this implies a workable system, there are still many problems which need to be resolved. Countries must give up a large degree of domestic policy autonomy. Are the major industrial powers prepared to subjugate their domestic objectives to international stability? History leads to some skepticism.

Policy coordination works fine when countries have common goals. The recent interest-rate reductions agreed to by the United States, Japan, and West Germany are an example of this. However, there will certainly be instances in which goals do not appear beneficial to all. An example is that of Japan's and West Germany's unwillingness to stimulate their domestic economies in order to reduce their trade surpluses. Both the Japanese and West German Governments are far less willing to risk inflation, even at the cost of economic growth, than is the United States. Thus, the key problem with this agreement is that, except for moral suasion, there is no mechanism of enforcement. *(Mathew Shane 786-1705 and David Stallings 786-1724)*

July, but the sectoral pattern showed a 181,000-job decline in manufacturing and a 1.2-million-job increase in service employment.

The merchandise trade deficit for the first 6 months of the year was considerably worse than during the same period in 1985. While housing starts boomed in the first half and auto sales were up slightly over 1985, these sectors were too small to boost overall growth.

The current estimate of real GNP growth during the first half of the year is 2.4 percent, but much of that growth was due to unintended inventory accumulation. Looking at final sales, real growth was 1 percent over the first half of the year, considerably under the 3.5- to 4.0-percent range envisioned by many analysts.

Business investment spending, rather than rising, fell a surprising 1.1 percent from its 1985 level and inventories piled up due to unexpectedly weak demand.

A Slip in the Oil Patch

One of the major reasons the first half of 1986 was weaker than anticipated was the abrupt drop in crude oil prices. From June 1985 to June 1986, oil prices fell nearly 70 percent, using the North Sea Brent benchmark crude price.

The immediate impacts of tumbling prices were layoffs and lower investment spending, setting off a round of negative multiplier effects in oil-producing States. Employment in mining, petroleum, and coal-product

production fell by about 126,000 from December 1985 to June 1986, about a 12-percent decline. Production in the oil and gas extraction industry fell 9 percent from December 1985 to May 1986.

The oil industry accounted for about 10 percent of all business spending on new plant and equipment in 1985. About 25 percent of the industry's 1986 spending plans were cancelled as prices fell. Over the first half of the year, real fixed nonresidential investment fell about \$5.5 billion, of which about \$3.1 billion was due to declines in petroleum exploration and drilling equipment. Even with falling interest rates, the decline in capital spending by the petroleum industry left overall capital spending weak.

Second-round effects from the oil layoffs are plaguing the States in which crude production is concentrated: Texas, Louisiana, California, Alaska, Oklahoma, and Wyoming. Together these States accounted for 21 percent of all retail sales in 1985, and over 25 percent of all housing starts. Sluggishness in overall U.S. retail sales, which rose 1.1 percent from January 1986 to June 1986, compared with 6.8 percent over the same period in 1985, is in some part due to loss in purchasing power in the oil-producing States. Although housing starts in these States have been brisk, they would have been even faster with more normal economic growth.

While the benefits of lower oil prices are asserting themselves slowly, and will ultimately outweigh the immediate negative impacts of the abrupt fall, much of the sluggishness of the first half is attributable to the shock to the oil industry.

Where is the Turnaround in Foreign Trade?

Although the dollar's decline was expected to bring some relief to the manufacturing sector by turning around merchandise exports and imports, the turnaround has yet to be seen in trade statistics. Over the first 6 months of 1986, the trade deficit averaged close to \$14 billion a month, up from the \$13.2 billion averaged during the last half of 1985. Without a recovering manufacturing sector, the expected faster growth of 1986 evaporates. What is so different about this trade deficit that makes it so hard to turn in favor of the United States?

One possibility is that there is nothing different, and that the expected turnaround is just around the corner. The worsening first-half trade balance could be just a manifestation of the J curve, and further evidence that the adjustment is on the way. The 4- to 6-quarter lag in volume adjustment is hardly precise, and the effect could take a few quarters longer.

This lengthening of the lag time could be due to changes in the foreign exchange market. Exchange rates are now more market-determined than before, and market participants may

take more time to read the price signals to make sure that exchange rate movements are not just transitory.

Further, there is some evidence that foreign exporters are cutting profit margins in an attempt to maintain their share of the U.S. market, just as they let their profit margins rise when the dollar rose in 1983 and 1984. These reasons suggest that trade volume changes should become apparent in the third and fourth quarters of this year, delaying the expected faster economic growth but not eliminating it.

There are some unusual aspects of this trade deficit, however, which may help to explain the sluggish response. Although the dollar has fallen overall, it has not fallen appreciably against those currencies which comprised about half of the U.S. merchandise import bill in 1985. For example, the U.S. dollar has not depreciated against the Canadian dollar. Canada alone accounted for about 25 percent of U.S. exports and 21 percent of imports in 1985. Currencies of other major suppliers of U.S. imports, such as Taiwan, South Korea, and Hong Kong, have not appreciated either.

What's Ahead?

The stage is still set for faster economic growth, only the performance is starting a little later than everyone thought. Lower oil prices have led to a virtually inflation-free first half of 1986, and have also reduced interest rates. Once the initial negative impacts of the oil-price decline on capital spending are past, lower interest rates should boost the economy.

Residential construction should continue to be brisk. As the manufacturing sector revives in the latter part of 1986 and into 1987, employment and personal income should grow. Real growth in 1986 could be about the same as 1985's 2.7 percent, with inflation around 3 percent and interest rates near current levels. With a shrinking trade deficit, real growth should accelerate in 1987, bringing faster disposable income growth and slightly higher interest and inflation rates.

What Could Go Wrong?

It is most likely that the economy will speed up late in 1986 and accelerate through 1987. As the first half of 1986

has shown, however, nothing is certain. There are several factors which will, over the next few months, help to determine whether growth slows or accelerates. Among them:

- Another abrupt decline in oil prices could send the 6 major U.S. oil-producing States into very severe straits and add stress to an already-burdened financial sector. On the other hand, if OPEC manages to curtail production and force prices up, real consumer and business income could be reduced.
- Responses to a larger-than-expected budget deficit for 1986 and 1987 could force considerable Federal spending cuts, which would have the immediate impact of weakening overall demand in the economy.
- Without solid foreign economic growth, the market for U.S. exports will be weaker than forecast, extending the time between the dollar decline and the trade-volume turnaround.

[Ralph Monaco (202) 786-1283]

Upcoming Releases from the Agricultural Statistics Board

The following list gives the release dates of the major Agricultural Statistics Board reports that will be issued by the time the October *Agricultural Outlook* comes off press.

September

- 2 Egg Products
- Poultry Slaughter
- 4 Dairy Products
- 5 Celery
- 10 Vegetables
- 11 Crop Production
- 12 Turkey Hatchery
- 15 Milk Production
- Cattle on Feed
- 18 Hop Stocks
- 19 Citrus Fruits
- Catfish
- 22 Hogs & Pigs
- Livestock Slaughter
- Cold Storage
- 23 Eggs, Chickens, & Turkeys
- 26 Potatoes & Sweetpotatoes
- 29 Peanut Stocks & Processing
- Soybean Stocks
- 30 Egg Products
- Agricultural Prices

Conservation Reserve Signup Mirrors Successful Soil Bank Program

The Conservation Reserve Program (CRP) has enrolled just over 3.8 million acres in 1986.¹ The first signup (March 1986) received bids on 4.8 million acres, but only 838,000 were accepted. During the second signup (May 1986), 4.6 million acres were bid, and 3 million were accepted. Bid acceptance was higher in the second period because farmers had a better idea of the rate the Government would pay. A third signup period was held in August. Results will be known by the October *Agricultural Outlook*.

The enrollment goal for the 1986 crop year is 5 million acres, and there is concern over the program's ability to reach its goal of 40 to 45 million acres by 1990. A look at the way the CRP's predecessor, the Soil Bank, began may shed some light on the current and future performance of the CRP.

Soil Bank

The Soil Bank subtitle of the Agricultural Act of 1956 contained a long-term retirement program (Conservation Reserve, SBR) and a shorter-term program (Acreage Reserve Program, ARP). The ARP was terminated after 3 of its intended 4 years because Congress felt it was too expensive. In fact, production of allotment crops continued to increase when the ARP was in effect, despite the 12.2-, 21.3-, and 17.2-million-acre enrollments for 1956, 1957, and 1958, respectively. The respective Government outlays were \$260, \$614, and \$696 million.

¹ Acreage based on accepted bids. Acreage placed under contract will differ somewhat due to ground checks to determine field sizes, and whether fields qualify based on erosion rates and other factors.

Soil Bank Signup Followed Theoretical Pattern. . .

Cumulative enrollment, million acres

. . . Likewise, Conservation Reserve Program Signup Is Expected to Accelerate

Cumulative enrollment, million acres

The Soil Bank's Conservation Reserve Program provided 3- to 10-year contracts (10 to 15 years for trees). The SBR differed from the ARP by having a lower payment rate per acre and a longer contract period, and by allowing enrollment of any land used for field crop production. Lands placed into the SBR could not be used for haying, grazing, Christmas trees, or fruit production.

Soil Bank participants were eligible for two types of payments: annual payment, which represented the rent paid for keeping the land out of production, and cost-share payments, to help defray the cost of conservation practices.

In addition, participants who enrolled their whole farms were given a 10-percent bonus. Enrollees were given 80 percent of the cost of establishing permanent vegetation. Farmers could enroll as much land as desired, with no county-wide limits.

Conservation Reserve Program

The CRP of the 1985 Food Security Act is designed to reduce excessive wind and water erosion on highly erodible cropland. Farmers may receive annual rental payments, plus 50 percent of the cost of establishing a permanent cover crop. Rental payments are determined by the amount farmers bid to put cropland into the CRP. Enrollment in the CRP is for 10 years. No more than 25 percent of the cropland acreage in any county may be enrolled, and farmers can enroll only those fields containing at least two-thirds of the cropland considered highly erodible.

The CRP acreage is removed from a farmer's productive cropland base. Also, farmers' base acreage is reduced by the ratio of CRP base acres to total cropland.

The Adoption Process

The rate at which a new program, technology, or idea (innovation) is accepted over time is known as the adoption process. The CRP and SBR programs can be thought of as innovations that farmers with marginally productive croplands can adopt. With few exceptions, adoption follows a normal distribution. That is, adopter distributions follow a bell-shaped curve over time, cumulatively forming an S-shaped curve. Signup for the SBR followed this pattern.

If the economic climate, program characteristics, and promotional efforts for the CRP are the same as for the SBR, then the rate of adoption for the CRP should be similar to that of the SBR. Therefore, the differences between these factors can reveal possible differences in the adoption rate.

Economic Climate

Comparing the 5-year period before the SBR with the 5-year period before the CRP yields the following:

- Farmland values declined at an average annual rate of 6 percent over the 1981-86 period. In 1951-56, they rose at an average annual rate of 4 percent.
- The farm sector debt-to-asset ratio was increasing from 1951-56 because of rapid capitalization. In 1981-86, the increase was attributable to falling asset values.
- In both periods, declines in the parity ratio indicated a continuous decline in the price of farm products relative to the price of products in other sectors. The financial health of the farm sector, based on this indicator, showed an almost continuous deterioration prior to implementation of the SBR and CRP.

Overall, the farm sector's financial situation is much worse today than in the period preceding and including the SBR. Where the current expected return to land and management (including Government support payments) is less than

TREE PLANTING

Tree planting under the CRP will dwarf major tree-planting efforts of earlier eras. The Civilian Conservation Corps, for example, planted 2.3 million acres to trees over a 9-year period in the 1930's and early 1940's; under the Soil Bank Program, 2.2 million acres were planted to trees in a 7-year period from 1956 to 1962.

In the March 1986 signup, bids for trees were accepted on 131,000 acres, and in the May 1986 signup, another 191,000 acres of trees were added. The CRP accomplished almost 5 percent of its 5-million-acre tree goal in its first year; trees were 8.4 percent of first-year bids. (Robert J. Moulton (202) 235-1697)

Tree Planting by CRP Signup

Signup	Thousand acres		
	All	Trees	Per- cent trees
March 1986	828	131	15.8
May 1986	3,001	191	6.4
Total	3,829	322	8.4

what could be gained by enrolling in the CRP, farmers will participate. Where current expected returns exceed returns from enrollment, participation will depend upon the farmer's risk preference, cash flow requirements, and liquidity. Thus, farmers who expect decreasing returns may enroll their land in the CRP.

Who would be likely to participate? In general, those farmers most likely to shift from intensive, crop-management systems to less intensive forage-management systems would probably have made the conversion over time without any incentives. Based on the characteristics of SBR participants, the most likely CRP enrollees will be farmers seeking to leave agriculture, farmers with beef or timber operations already in place, and farmers who would benefit from additional woodland stands, wildlife habitats, or erosion-reducing systems.

Farmers being faced with conservation compliance or new equipment purchases may consider enrollment as an alternative. Also, demand for red meat and dairy products increased during the 1951-60 period, while current expectations are far less promising. Some producers may use the CRP to exit. The current outlook for timber (particularly for softwoods) is very good, while the outlook was poor before and during the SBR signup period.

One of the most dramatic differences between the SBR and CRP is the relative complexity of the two programs. The SBR was a fairly straightforward program: farmers were offered a rental rate and could enter as many acres as they desired.

The CRP, however, requires farmers to determine the value of the land-use shift and bid against other farmers in the same area. Furthermore, farmers, with the assistance of USDA, have to determine what acres are highly erodible, the field boundaries that will allow at least two-thirds of the field to be predominantly highly erodible, and the acreage required to comply. Both programs were announced after the planting season had begun. For the CRP, farmers may have perceived Gramm-Rudman as a threat to annual payment amounts.

Disincentives To Enrollment

Current commodity programs encourage farmers to maintain a crop base. Since the CRP will reduce the crop base without additional compensation, it has a strong disincentive. Also, since little growth in livestock markets is expected, there is little incentive to convert cropland to pasture.

The perceived benefits of maintaining commodity bases will probably override all other variables in determining the CRP's relative advantage, giving a slower rate of adoption than predicted by the SBR rate. One factor may increase the adoption rate, though. The 1985 farm act is attempting to reduce deficiency payments over time. Thus, expectations for the deficiency-payment value of crop bases may decline. Similarly, removal of the ARP in 1959 dramatically increased signup for the SBR.

The conservation compliance provision, to become effective in 1990, will increase crop-base maintenance costs on about 120 million highly erodible acres. For these farmers, the CRP may become more profitable than attempting to maintain a crop base. Thus, the rate of enrollment may be slower in the first years, but higher in later years. This will occur because of the compliance provision and the gradual reduction of commodity deficiency payments.

Without a major shift in regional production patterns (such as the return of the Corn Belt as a major beef producer or a decrease in pivot irrigation in the Northern Plains), the CRP will remain incompatible with most current production systems. Farmers have made large investments in row-crop and small-grain production and harvesting equipment. Reducing the acreage of these crops would increase per-acre fixed costs and inhibit enrollment.

Finally, confusion surrounding the first two signup periods, coupled with the difficulty in determining acceptable bid amounts, probably contributed to a decision by some potential participants to wait for the later signup periods. As the signup methods become more understood, and information about acceptable bid levels becomes more widely known, participation is likely to increase.

In summary, several factors could speed the CRP adoption rate:

- First, eligibility is limited to 69.5 million acres. Expanding this by relaxing eligibility requirements would increase participation. The SBR was available to the entire cropland base.

- Second, reducing the value of base acreage through a reduction in commodity programs, implementing the compliance provision earlier, or providing enrollment bonuses would increase participation.
- Third, increasing the incentive to participate by offering or accepting bids at higher rental rates, allowing limited use of the land (such as grazing every third year, or haying in alternate years), or prohibiting the use of cropland eligible for the CRP as set-aside acreage would increase participation.
- Last, if the agricultural economy does not perk up faster, participation will grow even faster. *[Michael R. Dicks (202) 786-1404]*

1/ Retail costs are based on indexes of retail prices for domestically produced farm foods from the CPI-U published monthly by the Bureau of Labor Statistics. The farm value is the payment to farmers for quantity of farm product equivalent to retail unit, less allowance for byproduct. Farm values are based on prices at first point of sale and may include marketing charges such as grading and packing for some commodities. The farm-retail spread, the difference between the retail price and the farm value, represents charges for assembling, processing, transporting, and distributing these foods. 2/ Estimated weighted average price of retail cuts from pork and yield grade 3 beef carcasses. Retail cut prices from BLS. 3/ Value of carcass quantity equivalent to 1 lb. of retail cuts; beef adjusted for value of fat and bone byproducts. 4/ Market value to producer for quantity of live animal equivalent to 1 lb. of retail cuts minus value of byproducts. 5/ Represents charges for retailing and other marketing services such as fabricating, wholesaling, and in-city transportation. 6/ Represents charges made for livestock marketing, processing, and transportation to city where consumed.

Notes: Annual historical data on farm-retail price spreads may be found in Food Consumption, Prices and Expenditures, Statistical Bulletin 736, ERS, USDA.

*August 12, 1986 Supply and Demand Estimates. 1/ Marketing year beginning June 1 for wheat, barley, and oats, August 1 for cotton and rice, September 1 for soybeans, corn, and sorghum. October 1 for soybean meal, and soybean oil. 2/ Conversion factors: Hectare (ha.) = 2.471 acres, 1 metric ton = 2204.622 pounds, 36.7437 bushels of wheat or soybeans, 39.3679 bushels of corn or sorghum, 45.9296 bushels of barley, 68.8944 bushels of oats, 22.046 cwt. of rice, and 4.59 480-pound bales of cotton. 3/ Includes diversion, PIK, and acreage reduction programs. 4/ Includes imports. 5/ Season average. 6/ Statistical discrepancy. 7/ Includes seed. 8/ Average of crude soybean oil, Decatur. 9/ Average of 44 percent, Decatur. 10/ Upland and extra long staple. Stock estimates based on Census Bureau data which results in an unaccounted difference between supply and use estimates and changes in ending stocks.

Information contact: Sam Evans (202) 786-1840.

E = Estimated. P = Projected. F = Forecast. 1/ Excludes intra-EC trade. 2/ Where stocks data not available (excluding USSR), consumption includes stock changes. 3/ Stocks data are based on differing marketing years and do not represent levels at a given date. Data not available for all countries; includes estimated change in USSR grain stocks but not absolute level. 4/ Calendar year data. 1981 data correspond with 1980/81, etc.

Real 2/	100	100	98	97	97	97	95*	94*	93*	92*	92*	90*

1/ Nominal values are percentage changes in currency units per dollar, weighted by proportion of agricultural exports from the United States. An increase indicates that the dollar has appreciated. 2/ Real values are computed in the same way as the nominal series, adjusted for CPI changes in the countries involved.

*Preliminary; assumes the same rate of CPI increase/decrease as the previous six months. n.a. = not available.

ERS DATABASES FOR SALE

The Economic Research Service has a variety of computerized databases covering important elements of agriculture here and abroad. These series should be of considerable interest to those associated with government, commercial, and university projects.

DESCRIPTION

FARM INCOME. Statistics at the United States level, 1910-84, and state and regional levels, 1949-84, including net farm income, cash receipts by components, production expenses, capital expenditures, off-farm income, and other material. Contact: Gary Lucier (202) 786-1809.

FARM REAL ESTATE. Value of land and buildings on a per acre and per farm basis, and real estate debt and taxes, 1950-85, for the United States and 48 states. Contact: Gene Wunderlich (202) 786-1425.

IRRIGATED FARMS. Special tabulations for irrigated farms from the 1982 Census of Agriculture, by type of organization, size of farm, market value of agricultural products for all farms and by principal source of irrigation water. Data for all harvested cropland irrigated and for specified crops by principal source of irrigation water. Series cover 17 Western states, Arkansas, Florida, and Louisiana individually and as a group; all other states as a group; and the United States in total. Contact: John Hanchar (202) 786-1410.

PESTICIDE USE AND MANAGEMENT. Summary data for 32 states on pesticide use and related items for major field crops, and pesticide expenditures on livestock. For each crop, pesticide active ingredients are reported by acres treated, frequency applied, quantity used, and application rates per acre. Contact: Herman Delvo (202) 786-1456.

FERTILIZER USE. Fertilizer use per acre by nutrient for major producing states, 1964-85, for corn, cotton, soybeans, and wheat. Contact: Harry Vroomen (202) 786-1456.

U.S. DRY BEANS. Domestic dry edible bean production and acreage data, 1970-85, and monthly data on imports and exports and weekly price data for 1981-85. Contact: Neilson Conklin (202) 786-1766.

POLICY IMPACT CODES. Classification codes for 2,443 non-metro counties identifying seven overlapping types according to their major economic base, presence of federally involved land, or population characteristics. Contact: David Weisblat (202) 786-3338.

LOCAL GOVERNMENT FINANCES. Revenues, expenditures, and debt, 1977-82, from the Census of Governments, with geographic location codes and BEA income and population data to facilitate the analysis of urban and rural fiscal trends. Contact: Rick Reeder (202) 786-1544.

EXCHANGE RATES. Real and nominal exchange rates for major U.S. customers and competitors of farm products, 1970-85. Annual and quarterly series for Argentina, Brazil, Canada, Japan, Mexico, and 11 other countries. Included are real exchange rate indexes for total agriculture and major commodities. Contact: David Stallings (202) 786-1624.

WORLD PRODUCTION INDEX. Production of grains and other agricultural commodities used in computing world production indexes, 1950-85, for 120 countries. Index numbers for calendar 1976-85 cover food and agricultural production

in total and per capita. Contact: David Stallings (202) 786-1624.

NIGERIAN GRAIN. Data on Nigerian grain production, trade, utilization, and prices, 1966-85, including foreign grain suppliers. Major macro-economic variables include GDP, exchange rates, balance of payments, and debt. Contact: Margaret Missaen (202) 786-1681.

NOTE: Disks are 5-1/4" DSDD; MS-DOS & PC-DOS compatible; tapes are 9-track, EBCDIC, unlabeled. Other specifications are listed below.

ORDER DIRECT AND SAVE

Check these new, reduced subscription rates now offered on a user fee, cost-recovery basis from USDA's Economic Research Service.

AGRICULTURAL OUTLOOK.

11 issues annually averaging 52 pages. Subscribe from ERS for \$26 domestic; \$32.50 foreign. USDA's official outlet for farm income and food price forecasts. Data and discussion of issues ranging from international trade to prospects for commodity supply and demand, food marketing, agricultural policies, and other major issues affecting agriculture and the economy.

FARMLINE.

11 issues annually averaging 20 pages. Subscribe from ERS for \$14 domestic; \$17.50 foreign. Farm economic information in an easily read style, reinforced with charts and statistics for those without time to review all the technical reports from ERS. Reports on all economic topics important to those involved in agriculture, with the focus on the causes and implications.

NATIONAL FOOD REVIEW.

Quarterly averaging 40 pages. Subscribe from ERS for \$9.00 domestic; \$11.25 foreign. The latest developments in food prices, product safety, nutrition programs, consumption patterns, marketing, and processing technology for those who manage, monitor, or depend on the Nation's farm system.

HOW TO ORDER. Check the box for each publication or insert the number of extra subscriptions you wish to order. Write one check or money order to cover total charges. You will receive a copy of the most current issue, and a letter acknowledging your subscription. *Do not send cash. No credit cards. Sorry, no refunds.* Foreign customers note: Only checks drawn on U.S. banks, cashier's checks, or international money orders accepted.
